Neal,

Please add me for 3 sets.

These filters may be manufactured by Tai-Saw, who I believe are in Tiawan.
www.taisaw.com
Model # TA0477A, under the RF SAW Filters section.
Don't know if they are available directly. Perhaps someone familiar with the language could check.

From: marcolanie
Topic: 8797 Message: 8797

Hi

The MSA documentation insists on the fact that C27 and R12 must be kept for PL0 1 ans PLO3. The chapter covering PLO2 operation says

"omit C27 and R12. The driver to this circuit will absorb the mismatch reflection. This may seem a like poor design but it is valid. It improves the noise performance of the PLL."

Is this sentence "up to date" or is it a fossil noise from a former modifications ? Should I keep C27 and R12 on PLO2 ?

Thanks in advance

Marc (lost in translation ;-o)

Subject: [spectrumanalyzer] 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

All,

Let me start out with the bottom line. With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").

A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the job. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.

I created a file folder called "1013 MHz SAW Filter"

http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/

on the group page for you all to look at. The folder contains various frequency responses, pictures of the PCB, and construction stage photos. I also included a data sheet for the SAW that was used. Basically, the design consists of three cascaded SAWs, a few PADs and an ERA-33 amplifier. If you look at the group file, you will get a good idea of the approach and performance.

I am curious if there would be any interest out there for putting together some sort of group buy for this filter. A group buy would be for the SAWs (three required/filter-I paid $5.75/each ordering in small quantity), a PCB (>$5.00/each), plus shipping. The quantity we order will obviously drive the SAW cost. The rest of the parts needed to complete the assembly (caps, resistors, connectors,etc.) are very similar to the MSA's current IF ERA-33SM based amplifier. If there is enough interest, I would be willing to facilitate the group buy of the SAWs and PCBs.

Before we formally begin a group buy, those of you out there with interest please post a response so we can get an idea of what quantities we may be talking about. BTW, Scotty is considering adding this to the formal SLIM list. He is working on putting the PCB layout, schematic and parts lists in the form consistent with what he uses for SLIMs.

Hi Marc,
 The original reason to delete C27 and R12 on all PLO modules was for power conservation and phase noise minimization. It does this.
However, during testing, I found that PLO1 and PLO3 harmonic and spurious was decreased a little with the components re-installed. It was not a big decrease, but enough to justify the re-installation. I could find no difference with or without in PLO2. Therefore, leave them out of PLO 2

Those are clearly excellent results. Although the cavity filter impresses the girls, it's making me rethink my bad experience with SAW devices in the past.

This is the manufacturer and they do have sales/distribution support in the U.S. Perhaps it may not be hard to scrounge some up on this side of the pond.

To: spectrumanalyzer@yahoogroups.com
Subject: [spectrumanalyzer] 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

All,

Let me start out with the bottom line. With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").

A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the job. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.

I created a file folder called "1013 MHz SAW Filter"

http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/

on the group page for you all to look at. The folder contains various frequency responses, pictures of the PCB, and construction stage photos. I also included a data sheet for the SAW that was used. Basically, the design consists of three cascaded SAWs, a few PADs and an ERA-33 amplifier. If you look at the group file, you will get a good idea of the approach and performance.

I am curious if there would be any interest out there for putting together some sort of group buy for this filter. A group buy would be for the SAWs (three required/filter-I paid $5.75/each ordering in small quantity), a PCB (>$5.00/each), plus shipping. The quantity we order will obviously drive the SAW cost. The rest of the parts needed to complete the assembly (caps, resistors, connectors,etc.) are very similar to the MSA's current IF ERA-33SM based amplifier. If there is enough interest, I would be willing to facilitate the group buy of the SAWs and PCBs.

Before we formally begin a group buy, those of you out there with interest please post a response so we can get an idea of what quantities we may be talking about. BTW, Scotty is considering adding this to the formal SLIM list. He is working on putting the PCB layout, schematic and parts lists in the form consistent with what he uses for SLIMs.

Neal

Topic: 8814 Message: 8814

Hello Group: Coax filter buyers note:

I have received orders for 13 coax filter units. Now this SAW filter turns up out of the blue.

Some coax buyers may be in a conundrum.

The Coax filter build is a hobby for me ($0 on my time) any profit is on the machined parts.

Therefore I will accept the cancellation for a coax filter order, but please let me know before 15 DEC.

Regards

Len Spyker

Hi Neal

I would be interested in 2 units.

It may be an advantage to the AU people if the ERA-33SM was included in the group buy. The Minicircuits representative in AU were very helpful and met the 'all the parts' quote offered by Minicircuits, however the cost for one off, low volume orders is much higher - not a complaint, just an observation.

Thanks

Marty

With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").
>
> A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the job. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.

Mark-

I'm just beginning the SLIM build and would like to be included in the group buy. Just let me know where the money is to be sent, and thanks for your efforts in developing this option.

Subject: [spectrumanalyzer] 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

All,

Let me start out with the bottom line. With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").

A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the jo! b. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.

I created a file folder called "1013 MHz SAW Filter"

http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/

on the group page for you all to look at. The folder contains various frequency responses, pictures of the PCB, and construction stage photos. I also included a data sheet for the SAW that was used. Basically, the design consists of three cascaded SAWs, a few PADs and an ERA-33 amplifier. If you look at the group file, you will get a good idea of the approach and performance.

I am curious if there would be any interest out there for putting together some sort of group buy for this filter. A group buy would be for the SAWs (three required/filter-I paid $5.75/each ordering in small quantity), a PCB (>$5.00/each), plus shipping. The quantity we order will obviously drive the SAW cost. The rest of the parts needed to complete the assembly (caps, resistors, connectors,etc.) are very similar to the MSA's current IF ERA-33SM based amplifier. If there is enough interest, I would be willing to facilitate the group buy of the SAWs and PCBs.

Before we formally begin a group buy, those of you out there with interest please post a response so we can get an idea of what quantities we may be talking about. BTW, Scotty is considering adding this to the formal SLIM list. He is working on putting the PCB layout, schematic and parts lists in the form consistent with what he uses for SLIMs.

8819. Hot Air Soldering

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-07 06:15:07 UTC
From: peepholenz
Topic: 8819 Message: 8819

This might be of interest for 3x3mm filters etc
Hot air soldering station for about $65US.

<http://www.ebay.com/itm/ATTEN-858D-SMD-Hot-Air-Rework-Station-Solder-858D-/110726694669?pt=LH_DefaultDomain_0&hash=item19c7d3470d>.

Same item also appears elsewhere on ebay.

I received mine a couple of weeks ago and have found it very easy to use - only on some old cellphone boards as a trial.
No idea how long it'll last....but at the price.....

Make sure you get one with the correct voltage though - mine needs 230v as the southern hemisphere electrons are only half the size of the US ones.
It arrived quite quickly,about 10days. It is small enough to easily fit on my rather messy workbench.

Looks interesting but here is how I did it and had fun doing so:

1. Got at Home Depot a small Wagner HT400 Heat Gun.
2. I got and Arduino PID controller (which does double duty at my toaster reflow oven) and rewired the Wagner's heating element.
3. I build my nozzles with light weight aluminum flashing (also from the Home Depot) and hold them with a small SS clamp.

BTW the Wagner gun is powerfull enough to heat up the back of a circuit board and easily recycle its components.

Every time I have bought chieeze stuff , I have regretted it .
Many times it just doesn't do the job , almost all the time , several
things go wrong early .
Making me tell myself never again .
There is a saying about quality tools ,
BITCH ONCE WHEN YOU BUY IT - higher price .
NOT EVERY TIME YOU USED IT - cheap chineeze junk .
In the long run you do a better job for less time and money , doing a bad
job , redoing that job and buying another tool every time it breaks .
That's aside from , talking work away from local manufacturing .

8834. Multiple saw filters?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-08 15:12:35 UTC
From: mdgolfbum
Topic: 8834 Message: 8834

Is there a reason to buy more than one kit if I only have a single MSA? Are the SAW filter kits useful in more than one place like a tracking generator or some other aspect of measurement when using the MSA?

My MSA kit is in the basement and not yet started.

Thanks

Jim ab3cv

One filter is all you need, to replace the cavity filter. I assume people ordering multiple kits have non-MSA uses in mind.

Neil,
Good job. I am interested in two sets.
A good discovery, makes the cavity filter eaiser. I remember the discussion a while ago. With the amplfier, although the insertion loss can be 0, but the noise figure might be around 7 to 8 dB, similar to the original cavity filter. Therefore, the overall noise floor of MSA will be similar to the one with cavity filter. The difference is the rejection, cavity filter has better rejection at 1034MHz (around 105dB or higher). I don't think we care about the difference between 95dB and 105dB. The small size is the real reason that I want to try this filter.
Thanks
Lin

having looked on the "original" manufacturers site Tai SAW is the manufacturer, golledge is "only" a disitributor.

What concerns me a bit: due to the very tiny structures on the SAW these filters can not withstand input powers above about 0 dBm. filters.

Overdriving these filters will cause a "slow" degaradation

Unfortunately there is no ifnormation on the data sheet about the maximum drive capability...

Hi Henning and All,
A 0 dBm maximum input to the SAW device is probably a good guess. This new assembly will have a 3 dB attenuator preceding the SAW. In the MSA, the assembly follows Mixer 1 (replacing the Cavity Filter). With this configuration, the maximum input to the MSA (for compression) is about -17 dBm. This means the maximum input to the SAW (during normal use) will be about -25.5 dBm
During MSA calibration, a maximum input could be +10 dBm. This means the input to the SAW will be about +.5 dBm.
So, there is no problem when used in the MSA. If it is used for some other project, a maximum input to the assembly should be specified as +3 dBm.
Scotty

From: Sam
Topic: 8774 Message: 8843

The insertion loss of Mixer 1 is about 6 dB for the actual mixer plus 3 dB for the input attenuator. And once you get to high level signals (approx. 0 dBm) you get about 0.5 dB additional output for 1 dB of additional input, so even with a ridiculously high input level such as 10 dBm I don't think you would get even 0 dBm out of Mixer 1 running to the SAW filter. I haven't seen the schematic, so I'm not sure how the internal amp in the filter fits into this analysis.

8844. Coax Filter build and 1013 MHz SAW Filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-09 14:39:08 UTC
From: marc olanié
Topic: 8844 Message: 8844

>I have received orders for 13 coax filter units. Now this SAW filter turns up out of the blue.

>Some coax buyers may be in a conundrum.

That☐s quite an understatement :-)

Dear Len

I must admit that I☐m a little bit puzzled. The price difference is important and the performances are almost the same. But the cavity filter is definitely more robust.

Anyway, I gave you my word, and I☐m still interested having a ☐full metal cavity☐

But if I☐m the only guy in town on the waiting list, I don☐t think it will worth the hassle. It will cost you time, energy, and I think the SAW filter will be ok form my MSA

So, I☐ll let you decide.

And please, don☐t hesitate if you decide to make a run of filter and if you need a Paypal order, I☐ll sent it to you a.s.a.p.

Cheers

Marc

Simon,
Yes the data sheet says max input is +10 dBm and it also says +5vdc. However, this is "maximum without destruction". They don't specify "maximum without changes to operating characteristics". Our (engineering) rule of thumb....don't operate a SAW device with a DC bias voltage on its input or output, and always keep the power well below maximums (at least 3 dB).
Scotty

Sam,

There is a rough (unlabled stuff) schematic in the file folder. Scotty is working on a "SLIM" version.

Neal

8847. Re: 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-09 17:23:59 UTC
From: Sam
Topic: 8774 Message: 8847

OK, I missed that. The arrangement is Input-Pad-SAW-Amp-SAW-Pad-Amp-Pad-Output, with 3 dB of loss in each pad and SAW and max gain in the Amp of perhaps 20 dB. This means the SAW after the Amp gets the strongest signal, which would be 14 dB above the filter module input. Using a crazy input of 10 dBm, which would create total loss in the Mixer 1 module of about 14 dB, this means a 10 dBm input could conceivably hit the max power level for that particular SAW.

I haven't tested the mixer module above inputs of 7 dBm, but it may be that by the time you hit 10 dBm the mixer output no longer increases much as the input increases, so maybe the mixer will act as a protective limiter.

While an input of 10 dBm would probably display as a mess of distortion on the MSA, it is conceivable that such an input could occur. Maybe an optional pad at the Amp output would be a good idea. I allowed for 20 dB of amp gain above; if it is only the more common 17-18 dB, the pad could be omitted but if it is the possible-but-not-likely 20-21 dB, the pad could be added.

Certainly at normal levels of use, which would not exceed 0 dBm at the MSA input, the SAWs will not be exposed to excess power.

I'm also curious why the overall filter ends up with a 3 dB bandwidth of about 14 MHz, when the spec for an individual filter is 1 MHz. Not that this is a problem, because the skirts are so steep, but it is curious. (I also just noted that the graph for a single SAW+Amp has a bandwidth of about 20 MHz--maybe the spec is a typo.)

And once you get to high level signals (approx. 0 dBm) you get about 0.5 dB additional output for 1 dB of additional input, so even with a ridiculously high input level such as 10 dBm I don't think you would get even 0 dBm out of Mixer 1 running to the SAW filter. I haven't seen the schematic, so I'm not sure how the internal amp in the filter fits into this analysis.

Topic: 8774 Message: 8848

Hi Sam,
 The data sheet specification for the BW is likely a "finger blunder" when it was released. They missed a digit. It should be 18 MHz, not 1 MHz. Even their swept data shows it to be about 18 MHz bandwidth (3 dB)
Scotty

OK, I missed that. The arrangement is Input-Pad-SAW-Amp-SAW-Pad-Amp-Pad-Output, with 3 dB of loss in each pad and SAW and max gain in the Amp of perhaps 20 dB. This means the SAW after the Amp gets the strongest signal, which would be 14 dB above the filter module input. Using a crazy input of 10 dBm, which would create total loss in the Mixer 1 module of about 14 dB, this means a 10 dBm input could conceivably hit the max power level for that particular SAW.

I haven't tested the mixer module above inputs of 7 dBm, but it may be that by the time you hit 10 dBm the mixer output no longer increases much as the input increases, so maybe the mixer will act as a protective limiter.

While an input of 10 dBm would probably display as a mess of distortion on the MSA, it is conceivable that such an input could occur. Maybe an optional pad at the Amp output would be a good idea. I allowed for 20 dB of amp gain above; if it is only the more common 17-18 dB, the pad could be omitted but if it is the possible-but-not-likely 20-21 dB, the pad could be added.

Certainly at normal levels of use, which would not exceed 0 dBm at the MSA input, the SAWs will not be exposed to excess power.

I'm also curious why the overall filter ends up with a 3 dB bandwidth of about 14 MHz, when the spec for an individual filter is 1 MHz. Not that this is a problem, because the skirts are so steep, but it is curious. (I also just noted that the graph for a single SAW+Amp has a bandwidth of about 20 MHz--maybe the spec is a typo.)

Neal

Please add me to the list for 2 sets.

Thanks, Jim, G3RTD

18 MHz makes a lot more sense. 1 MHz wasn't very credible.

Also, I described the arrangement as though there are two amps. Actual arrangement is:
Input-Pad-SAW-Amp-SAW-Pad-SAW-Pad-Output

Sam,

I did not spend a lot of time characterizing it yet, but The overall response actually looks very good when I put the Dual SAW module in front of the the AMP SAW module. I thought that might be pertinent to the discussion your having.

This means the SAW after the Amp gets the strongest signal, which would be 14 dB above the filter module input. Using a crazy input of 10 dBm, which would create total loss in the Mixer 1 module of about 14 dB, this means a 10 dBm input could conceivably hit the max power level for that particular SAW.
> >
> >
> >
> > I haven't tested the mixer module above inputs of 7 dBm, but it may be that by the time you hit 10 dBm the mixer output no longer increases much as the input increases, so maybe the mixer will act as a protective limiter.
> >
> >
> >
> > While an input of 10 dBm would probably display as a mess of distortion on the MSA, it is conceivable that such an input could occur. Maybe an optional pad at the Amp output would be a good idea. I allowed for 20 dB of amp gain above; if it is only the more common 17-18 dB, the pad could be omitted but if it is the possible-but-not-likely 20-21 dB, the pad could be added.
> >
> >
> >

> >
> >
> >
> > I'm also curious why the overall filter ends up with a 3 dB bandwidth of about 14 MHz, when the spec for an individual filter is 1 MHz. Not that this is a problem, because the skirts are so steep, but it is curious. (I also just noted that the graph for a single SAW+Amp has a bandwidth of about 20 MHz--maybe the spec is a typo.)

And once you get to high level signals (approx. 0 dBm) you get about 0.5 dB additional output for 1 dB of additional input, so even with a ridiculously high input level such as 10 dBm I don't think you would get even 0 dBm out of Mixer 1 running to the SAW filter. I haven't seen the schematic, so I'm not sure how the internal amp in the filter fits into this analysis.

8853. Re: [spectrumanalyzer] Re: 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-09 21:27:32 UTC
From: Geoff Moore
Topic: 8774 Message: 8853

Looking at the schematic in the files section, could the input from mixer1 be connected to J3, J4 connected to J1 and the output taken from J2. The pad preceding J4 could be bypassed and the pad following J1 increased to 6dB.

Same overall gain but lower input to SAW's. Only snag may be lack of pad to improve Z match from mixer to SAW.

My coax filter is no work of art but it works OK, the extra space gained by the new filter would allow for extra goodies.

Geoff

Thanks for the clarification and advice.

Scotty -- another question. The Rev A schematic has R11, 10 ohms, at the 10VDC input to the PWB. The picture appears to have a ferrite at that location on the PWB, while the PWB layout has the component labelled as FB1 and R11 is not included on the Rev A parts list.

Is the schematic correct? If so, the picture, PWB layout and parts list are in error?

Advice?

Thanks.

If you already built the MSA phase detector, the filters are going to look massive. I hope I never have to work on that module again.

Subject: [spectrumanalyzer] Hot Air Soldering

This might be of interest for 3x3mm filters etc
Hot air soldering station for about $65US.

<http://www.ebay.com/itm/ATTEN-858D-SMD-Hot-Air-Rework-Station-Solder-858D-/110726694669?pt=LH_DefaultDomain_0&hash=item19c7d3470d>.

Same item also appears elsewhere on ebay.

I received mine a couple of weeks ago and have found it very easy to use - only on some old cellphone boards as a trial.
No idea how long it'll last....but at the price.....

Make sure you get one with the correct voltage though - mine needs 230v as the southern hemisphere electrons are only half the size of the US ones.
It arrived quite quickly,about 10days. It is small enough to easily fit on my rather messy workbench.

Hi Geoff,
 It is a good question. Here are the numbers.
Using SWA Filter / Amplifier first, then the dual SAWS will increase the total gain of the MSA chain about 5 dB (or what your normal loss of your Cavity Filter is). It will increase the MSA noise floor about 2.5 dB. This is good compromise, more gain than noise.
 Now, using the dual SAWS feeding the SWA Filter / Amplifier has the same gain increase, 2.5 dB. However the MSA noise floor will increase (above using the Cavity Filter) about 14.5 dB. You will lose about 12 dB of dynamic range.

Hi Steve,
 The FB1 is most correct. However, it can be replaced with the 10 ohm resistor (or even larger) to help decrease low frequency input noise. Originally the bead was used to help prevent the very high harmonics of the PDM action (huge 10.7 MHz) from radiating from the input power line. If I were to do a re-design, I would use both in series.

Thanks for the clarification and advice.

Scotty -- another question. The Rev A schematic has R11, 10 ohms, at the

10VDC input to the PWB. The picture appears to have a ferrite at that

location on the PWB, while the PWB layout has the component labelled as

FB1 and R11 is not included on the Rev A parts list.

Is the schematic correct? If so, the picture, PWB layout and parts list

are in error?

Advice?

Thanks.

Thanks Scotty. Looks like there might be room on the PWB to install both components, I'll try to to that.

Topic: 8844 Message: 8860

Hello Group: Notice to the N buyers of my coax filters.

Do not worry, whatever qty the coax buying fraternity needs (where N >= 1)
, I will supply it.

It is a handmade product so how many I make is not an issue.

There are no hard feelings and I might even buy a SAW filter or 2 myself
(grin).

True story:

A few moons ago I did send various SAW data sheets (another brand) to Scotty
and asked about their suitability as a coax replacement.

Typical engineer doing his/her self out of a job !

But Scotty was not keen on them.

Life has ironic moments doesn't it?

Regards Len

Hi All,
I published a new web page for the SAW Filter Amplifier.
http://www.scottyspectrumanalyzer.com/slim_sfa_1013.html
Neal's pictures and plot results are posted there.
Neal will be sending me his SAW devices for further testing. I will update the web page as my testing progresses.

Hi Neal,

Adendum.

Two kits, one with filter SAW amplifier and the other with two filters SAW.
If it's possible ?
Thanks for all.
Regards.

From: Martin
Topic: 8865 Message: 8865

Hi Scotty and all

I have done a bit of snooping on the groups messages and have found a thread chatting about a software controlled RF band switch, but could not find it actually implemented.

I am lazy and would like to remove the 1G/3G - 2G patch arrangement, switching it with relays via the software (rather than a user operated switch).

Do any outputs on control board change with the software band selection?

Regards

Marty

Hi Marty,
Yes, they do. They are implemented using the SLIM Control Board. They also work with USB addition.

From: Sam
Topic: 8865 Message: 8867

U4 on the control board has the following bits:

P4-1 = Ground
P4-2 = D0 VS0 Video Selection
P4-3 = D1 VS1 Video Selection
P4-4 = D2 BS0 Band Selection, low order bit
P4-5 = D3 BS1 Band Selection, high order bit
P4-6 = D4 FR DUT Direction, Forward (0) or Reverse
P4-7 = D5 TR VNA Selection, Transmission (0) or Reflection
P4-8 = D6 Spare
P4-9 = D7 PS Pulse Start (a/k/a Latch Pulse), common to all latching relays. Normally high; pulsed low for 2-20 us to trigger relay latching.

You use the PS signal to initiate latching if you use a latching relay. Otherwise, just use BS0 and BS1 (=binary 1, 2 or 3). If you aren't switching filtering or some such thing, 1G and 3G are the same thing, so the low order bit BS0 is all you need for control, with 1=1G/3G and 0=2G.

A coax relay may be convenient, but you don't really need one. A single RF switch like the PE4251 will provide all the isolation you need. Someone (I forget who) recently had the idea of putting an RF switch on the diplexer board. I don't know if he ever actually did that.

Sam W.

8868. Re: [spectrumanalyzer] Re: Band selection and the control board

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-10 15:04:00 UTC
From: Jim Hontoria
Topic: 8865 Message: 8868

I placed the PE4251 in a small board together with the diplexer. A very compact solution. Somewhere I have two of these boards for anyone interested.

Could you do the filter with five (5) cavities? i am thinking about a preamp followed by it.

The SAW filter may be for portable MSA.
For desktop MSA, I think the original cavity filter might be better.

RF test equipment needs some weight, if it is too light, the RF cable could hold the equipment in air (or dominates equipment location), and it is hard to use. Cavity filter not only has better performance, but also has the desired weight.

Cavity filter is one of the major arts of the MSA design, I learnt a lot from this cavity filter. I did some tests on this cavity filter recently, the tests show that with some small structure change (make it simple), this filter can be a tunerable cavitifilter from 950MHz to 2.1GHz (I did not try above 2.1GHz, I think it still works very well), which will give us a lot of flexibility if you really want to use the MSA as your RF receiver design platform.

It seems to me that the combination of the narrower bandwith of the cavity with the rejection of the saw is the ideal solution. I wouldn' throw away those cavities.

I have made 2 cavity filters to clean up a doubled 245 MHz OCXO, as well as a 4 cavity design to clean up another that is quadrupled to 980 MHz for an AD 9910 clock. I'm a bit surprised that you can get it up to 2 GHz, but it sure should operate at 3 GHz with the tuning rods acting as 3/4 wave rods.

W4ZCB

From: Sam
Topic: 8861 Message: 8873

Jim,
I had a similar thought, that you could use the single SAW+amp, followed by a cavity two-holer. I believe you can get 50 dB rejection from each. That would greatly simplify the cavity filter and give a response that would be narrower at the top, which I think is helpful for some spurs.

Even better, perhaps, is to do cavity(2 hole)-amp-SAW-pad. That creates just 2-4 dB of loss before the amp. The ERA-33 may have too much gain for this arrangement, but I'm sure a suitable amp could be found.

8874. Re: SAW Filter Amplifier

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-11 00:36:26 UTC
From: Sam
Topic: 8861 Message: 8874

Scotty and Neal,
I guess the problem with my previous post is that the single SAW+amp has a bump on the upper side that degrades it near 1034 MHz. So I revise my suggestion to this arrangement: pad-SAW-amp-cavity(2 holer)-pad-SAW-pad. Basically, this just replaces the second SAW with a 2-hole cavity filter. This also alleviates any concern over the SAW following the amp receiving too much power. In fact, given the saturation level of the ERA-33, and the loss in the cavity and the subsequent pad, it may be impossible for the final SAW to receive too much power. (We'll call that "Too protected to fail.")

To work at 2GHz, the rods have to be tunable.

If we care about the 2.5dB noise floor increase, maybe we can use a better LNA. Several month ago, MA-COM show me a LNA, MAAL-010570£¬ NF is around 0.8dB at 1GHz. IP3> 34dBm. ERA-33 has 3.3dB NF at 1GHz, if we replace it with MAAL-010570, we can get the noise floor down by about 2.5dB.

If we use 2.5dBpad + SWA + MAAL010570 + SAW + 3.5dBpad + SAW+3.5dBpad
We will get exact same noise floor as the original cavity filter (Noise figure 7.16dB, gain =0dB), according to the calculation.

Hi Lin,
 I don't think we are that concerned with a few more dB of noise. A perfect amplifier in this position would have the best noise figure and an output compression of less than +10 dBm. This would insure a safe level to the next SAW.

Lin,
I cannot find the MAAL-010570. Do you mean the MAAL-010705? This would require a redesign of the board.
In the present design there are provisions to add a 2 dB pad between the amplifier and following SAW filter. The total noise presented to the input of Mixer 2 would be the same as using the cavity filter. The replacement modules would then have a gain of -2 dB.
 This would still be a total MSA gain improvement over the Cavity filter, but with the same noise level.
  There are several schemes to use here. Experementation is fun.

Scotty

If we use 2.5dBpad + SWA + MAAL010570 + SAW + 3.5dBpad + SAW+3.5dBpad

We will get exact same noise floor as the original cavity filter (Noise figure 7.16dB, gain =0dB), according to the calculation.

Scotty
MAAL-010570 might be a new part, and the datasheet is not published yet. I can email it to you tomorrow. The downside is that its footprint is different from EAR-33+.

With the SAW filters, I was wondering if the maximum power at MSA input could get about 7dB worse. The maximum power is limited by the final RBW crystal filter, i.e. we do not want to overload the crystal filter. The power at crystal filter input would be 0dBm (or so). If we increase 7dB gain (it was -7dB with cavity filter, now we change to 0dB with SAW) in the FE path, that means we have to drop the maximum input power by 7dB. If the original dynamic range is -6dBm to -110dBm , with the SAW replacement, the dynamic range could change to -13dBm to -107.5dBm, this is still my guess, need to verify with test. -13dBm may not a bad number for home made SA.

A possible way that we make the dynamic range a little bit better could be that we put 10.7MHz, 1 (or 2) MHz BW BPF at outputs of IFA to suppress the noise level out band, in this way, we hope the total noise power arrives at crystal filter can be a little bit lower.

The IFAs have LPF at output, the BW might be around 40MHz (if I remember correctly), it is a little bit wide. If we can put a ceramic 1MHz BPF noise filter (or the widest RBW filter) between IFA1 and IFA2, I would expect the noise floor between 0-40MHz at crystal filter input would drop a lot. As the input level at new added BPF input is 18dB lower than the final crystal filter, it won't be overloaded. Maybe we can put one more this kind of filter between mixer 2 output and IFA1 input to see if it helps. Again, this is just some brain storming, I did not test them.

From: Sam
Topic: 8774 Message: 8881

Scotty,
Here is a nice compromise amp: the Minicircuits LEE-39. It's a 3 mm square package with leads at the corners, but it appears that if you place it at an angle the corners will line up with pads designed for the ERA.

Noise figure=2.4 dB, current=35 mA, gain=21 dB, P1dB=11 dB, and both input and output return losses exceed 25 dB. Unless OIP3 is a big concern, it could even be operated at 28 mA, lowering P1dB to 8 dB, without much change to other characteristics. (The data sheet itself doesn't contain much of this info; you have to click Download Graphs.)

Using your present SAW design, this would give a net 3 dB gain for the filter module. Or that extra gain could be sacrificed with a pad on the amp output, for additional protection of the SAW.

I researched some low noise amps, and the cost of reducing the noise figure by 1.5-2 dB seems high: large current draw, horrible return losses (which might affect the filter performance), and high P1dB levels which could zap the SAW. Not to mention 3 mm packages with four leads on a side.

Sam W.

>
> All,
>
> Let me start out with the bottom line. With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").
>
> A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the job. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.
>
> I created a file folder called "1013 MHz SAW Filter"
>
> http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/
>
> on the group page for you all to look at. The folder contains various frequency responses, pictures of the PCB, and construction stage photos. I also included a data sheet for the SAW that was used. Basically, the design consists of three cascaded SAWs, a few PADs and an ERA-33 amplifier. If you look at the group file, you will get a good idea of the approach and performance.
>
> I am curious if there would be any interest out there for putting together some sort of group buy for this filter. A group buy would be for the SAWs (three required/filter-I paid $5.75/each ordering in small quantity), a PCB (>$5.00/each), plus shipping. The quantity we order will obviously drive the SAW cost. The rest of the parts needed to complete the assembly (caps, resistors, connectors,etc.) are very similar to the MSA's current IF ERA-33SM based amplifier. If there is enough interest, I would be willing to facilitate the group buy of the SAWs and PCBs.
>
> Before we formally begin a group buy, those of you out there with interest please post a

response so we can get an idea of what quantities we may be talking about. BTW, Scotty is considering adding this to the formal SLIM list. He is working on putting the PCB layout, schematic and parts lists in the form consistent with what he uses for SLIMs.

From: Len
Topic: 8883 Message: 8883

Hello Group

When all the dust settles on the SAW design I will happily make 1-2-3-4 TUBE Coax cavity filters

What a win-win situation!

Provisional price; 2 TUBE KIT: U$28, Assembled and tested U$48.

Plus about U$15 postage from Perth Australia.

I assume these are still at 1.013 GHz ??

Other frequencies +/- 30% should be easy to do.

I am also assuming a simple linear scaling in all lengths? Including the coupling loop height?

Can a guru tell me this is true or not?

I am making a custom 4 tube at 1.0453 GHz, all the lengths cut ~3% shorter.

I will be testing it out tonight. I will report what the tunable range with the screws is.

Regards

Hi Len,
 Linear scaling of the stub lengths is certain. As frequencies go higher, the outside cavity length can be reduced, but you will not see any affect.
 Scaling the hairpins would be logical. However, this area is really more voodoo that science.

8888. Amp+Cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-12 15:34:27 UTC
From: Sam
Topic: 8888 Message: 8888

Here's an idea for significantly reducing the noise floor of an existing MSA. Use the SAW+amp module (but without the input pad) ahead of your cavity filter. The cavity output will be increased enough that the noise of the existing IF2 amp drops out of the equation, to be replaced by the identical noise of the amp in the SAW module. If your cavity filter and Mixer 2 each have 6 dB loss, you will be moving the amp 9 dB (12-SAW loss) up the signal chain and will get approximately 9 dB of noise improvement. (Noise reduction will also depend on how much noise comes out of Mixer 1.)

The SAW filter in this case is serving merely to eliminate strong signals far from 1013 MHz so IMD doesn't create an in-band signal; the cavity filter does the serious filtering. Thus, the profile of the SAW response is not very critical, which is why I think the input pad is likely not needed. Alternatively, you could keep the input pad, dropping 3 dB of the noise improvement. In that case, you would likely get by with a 3-cavity filter.

But if you already have the cavity filter, just adding the SAW+Amp in front of it is a simple modification.

I don't think this will increase dynamic range, because what you gain at the bottom you will lose at the top. But this would be particularly handy for VNA use, where you usually don't encounter input signals higher than the TG signal (and if you do you can easily attenuate them), so the very top end is not used. Or for SA use when looking for weak signals.

On top of the noise improvement, this should reduce all spurs other than those created by leakage through the cavity filter, by boosting the level of actual signals.

Neal or Scotty, maybe you could give this a try.

An alternative to this is to use two 2-cavity filters with the amp between them. I believe this would be much easier to build and tune than a 4-cavity filter.

Sam W.

P.S. This probably also requires that you reduce the gain of the IF2 amp, perhaps by simply bypassing half of it.

> The SAW filter in this case is serving merely to eliminate strong signals far from 1013 MHz so IMD doesn't create an in-band signal; the cavity filter does the serious filtering. Thus, the profile of the SAW response is not very critical, which is why I think the input pad is likely not needed. Alternatively, you could keep the input pad, dropping 3 dB of the noise improvement. In that case, you would likely get by with a 3-cavity filter.
>
> But if you already have the cavity filter, just adding the SAW+Amp in front of it is a simple modification.
>
> I don't think this will increase dynamic range, because what you gain at the bottom you will lose at the top. But this would be particularly handy for VNA use, where you usually don't encounter input signals higher than the TG signal (and if you do you can easily attenuate them), so the very top end is not used. Or for SA use when looking for weak signals.

Scotty
The original cavity filter has -7.1dB gain, and 7.1dB NF. To replace the cavity fitler with SAW, we need to create similar gain and NF to not change the dynamic range and noise floor significantly. As we use amplifier ERA-33+, we introduce noise into the system, therefore, the noise figure will be worst (means greater) than 7.1dB, if we want to keep a gain as -7.1dB.
Under the constrain of gain -7.1dB, try to minimize NF, here is what I got:

SAW + EAR33 + SAW + 8.4dB pad, +SAW +8.4dB pad

This will give us -7.1dB gain and 9.3dB NF. This means the noise floor will increase about 2dB, or dynamic range losses 2dB at bottom, which is not a significant change from the original design.

If we use MA-COM LNA,

SAW + MAAL010570 + SAW + 8.4dB pad, +SAW +8.4dB pad

we can get -7.1dB gain and 7.44dB NF. I don't think we care the difference for a 0.34dB noise floor increase.

Lin

There is no need to put an extra pad in the SAW module just to keep the noise floor the same. A lower noise floor is good. While it shifts the dynamic range downward, you can always move it back up if you want by adding an attenuator on the MSA input.

It would be a simple matter to look at what happens to the noise floor when the SAW module is put in place. I have limited faith in noise calculations.

Sam W.

Sam
If we put the pad at amplifier input (or MSA input), the overal noise figure will get worse.

If you want to add some attenuation to avoid maxing out on the high end, I think the place to do it is the IF2 amp, not the SAW amp. That way you keep the signal level higher at the IF2 amp input.

In any case, I think the way to proceed is to install the SAW module as designed, see what noise floor and high end you get, and tinker from there.

Sam W.

The best place for this 7.1 dB attenuator should be right at crystal filter RBW input, because the gain of IF1 and IF2 will help to get beter overall noise figure.

The maximum power is limited by the final RBW crystal filter, i.e. we do not want to overload the crystal filter. The power at crystal filter input would be 0dBm (or so). If we increase 7dB gain (it was -7dB with cavity filter, now we change to 0dB with SAW) in the FE path, that means we have to drop the maximum input power by 7dB. If the original dynamic range is -6dBm to -110dBm , with the SAW replacement, the dynamic range could change to

> > > > > >
> > > > > > The IFAs have LPF at output, the BW might be around 40MHz (if I remember correctly), it is a little bit wide. If we can put a ceramic 1MHz BPF noise filter (or the widest RBW filter) between IFA1 and IFA2, I would expect the noise floor between 0-40MHz at crystal filter input would drop a lot. As the input level at new added BPF input is 18dB lower than the final crystal filter, it won't be overloaded. Maybe we can put one more this kind of filter between mixer 2 output and IFA1 input to see if it helps. Again, this is just some brain storming, I did not test them.

The attenuator needs to be late in the amplification chain, but not so late that an amplifier gets overloaded. I think the perfect place would be between the two halves of the IF2 amp.
Sam W.

8897. 1.0453 GHz Coax filter results

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-13 02:41:00 UTC
From: Len
Topic: 8897 Message: 8897

Hello Group

All the 1.0453 GHz parts lengths were shortened by 3% (up 32 MHz) from the normal 1.013 GHz standard sizes.

This is based on my assumption of linear scaling.

I can tune the 4 tube 1.0453 GHz Coax cavity filter up to 1.054 GHz and down to 0.990 GHz while still working properly

Up 9 MHz and down 55 MHz seems to me the inner post length is still a bit too long.

I am not sure if the tuning Center Point is supposed to be at 1.0453 GHz or not.

Whether having less tuning screw stub poking inside the cavity is a good thing or not?

If there is a next time I will shorten them another 2%. The old suck it and see method.

Regards

Len Spyker

8898. Re: 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

Here is the updated calculation:
1) SAW + EAR33 + 4.7dB pad + SAW + 3dB pad, +SAW
2) Put a 9 dB pad between IFA1 and IFA2
In this way, the maximum power level at MSA input will be same, while the noise floor will drop about 6.8dB. This means the dynamic range is increased with the SAW filters.

Lin

Hi Len and All,
"Whether having less tuning screw stub poking inside the cavity is a good thing or not?"

A Coaxial Cavity Filter without a tuning screw will exhibit slightly less insertion loss and narrower bandwidth (higher Q). It will also be less susceptible to temperature changes (tuning drift). So for best performance, the stubs need to be just a tiny bit shorter than the electrical length so that only a very small amount of tuning screw (end capacitance) is needed to tune it true.
Harold built his without any tuning screws. He threaded the stubs and tuned by changing the internal length of the stubs.

Topic: 8888 Message: 8900

If we can change to the following configuration, we can get 0dBm to -114dBm dynamic range, with very good linearity.

1) SAW (can be replaced with 1-pipe cavity) + ERA 33 + 4-Pipe Cavity
2) Set IFA1 gain = 7.4dB,
3) Move IFA2 to the place between RBW filters and log detector, and add a widest RBW as noise filter at its output.

The overall (from MSA input to log detect input) gain will be 15dB, overall NF=15.5dB. MSA input range: 0dBm to -114dBm
calculated noise floor: -114dBm

The linearity from 0dBm to -10dBm will be very good.
Below -105dBm, the log detector has some non-linearity (That area is between -90dBm to -100dBm on log detector's V_dB curve, which is still useful).

Lin

> >
> > Here's an idea for significantly reducing the noise floor of an existing MSA. Use the SAW+amp module (but without the input pad) ahead of your cavity filter. The cavity output will be increased enough that the noise of the existing IF2 amp drops out of the equation, to be replaced by the identical noise of the amp in the SAW module. If your cavity filter and Mixer 2 each have 6 dB loss, you will be moving the amp 9 dB (12-SAW loss) up the signal chain and will get approximately 9 dB of noise improvement. (Noise reduction will also depend on how much noise comes out of Mixer 1.)
> >
> > The SAW filter in this case is serving merely to eliminate strong signals far from 1013 MHz so IMD doesn't create an in-band signal; the cavity filter does the serious filtering. Thus, the profile of the SAW response is not very critical, which is why I think the input pad is likely not needed. Alternatively, you could keep the input pad, dropping 3 dB of the noise improvement. In that case, you would likely get by with a 3-cavity filter.
> >
> > But if you already have the cavity filter, just adding the SAW+Amp in front of it is a simple modification.
> >
> > I don't think this will increase dynamic range, because what you gain at the bottom you will lose at the top. But this would be particularly handy for VNA use, where you usually don't encounter input signals higher than the TG signal (and if you do you can easily

attenuate them), so the very top end is not used. Or for SA use when looking for weak signals.

I tried without top tuning screw and just used a long screw as stub tune from bottom, it works well. In theory, this would get highest Q, and best rejection at 1034MHz. Also, the cavity filter will become a tuneable filter, can work from 970MHz to 2.1GHz.

Hi Scotty. Yup, the threaded stub was cool, but for "fineness" of tuning, I had to use a 1/4 x 36 tap and die, and the lock nut had to be really honked down. The bottom of the stub is REALLY the high current point! Silver soldered after getting it right made a fair sized improvement.

Regards

W4ZCB

Hi Len and All,
"Whether having less tuning screw stub poking inside the cavity is a good thing or not?"

A Coaxial Cavity Filter without a tuning screw will exhibit slightly less insertion loss and narrower bandwidth (higher Q). It will also be less susceptible to temperature changes (tuning drift). So for best performance, the stubs need to be just a tiny bit shorter than the electrical length so that only a very small amount of tuning screw (end capacitance) is needed to tune it true.
Harold built his without any tuning screws. He threaded the stubs and tuned by changing the internal length of the stubs.

Yes. The entire stub was threded. Works very well. You might remember that day I asked you about if we can change this cavity filter to a band stop filter. After that, I spent some time to think about this filter, and eventually, I figured out how it works. Base on how it works, I found if we change the stub to threaded, it will be a tuneable filter. The insertion loss will not change from 970MHz to 2.1GHz, from what I tested with a 1-pipe cavity filter.
Based on what I figured out, there are some other change we can do, such as we can make this filter length shorter (cut to half), or we can also tune to 500MHz with the original Length....

I would have assumed that the thread would introduce considerable
surface field non-linearity and as such reduce the filter Q.

Harold only threaded a small portion of the inner stub. One of the comments I made to him was, "Threading actually increases the surface length of the stub. Will this affect the electrical length?" I believe we agreed that if this were a much higher frequency filter, the skin effect would be significant and the extra surface length would alter the design. But, at 1 GHz, skin effect is not significant.
  Because this type of Coaxial Cavity Filter is not in wide usage in the electronics world, we MSA builders are learning something new every day.
 Definitely, fun stuff.

You might be right. I only did some prelimiary tests and did not get that detailed data. In my test, I just use thread steel stub. I even use steel metal as end plate for experiment. I did get higher insertion loss for 1-pipe cavity, about 4.x dB. As my application does not care the insertion loss, I did not try brass. If we change to brass, I would expect 2 dB or 1.8dB.
I measured with HP8753ES (VNA). I will upload some results later.

Will this affect the electrical length?" I believe we agreed that if this were a much higher frequency filter, the skin effect would be significant and the extra surface length would alter the design. But, at 1 GHz, skin effect is not significant.

Lin,
In theory, steel should be terrible, because skin depth is reduced by permeability, so the effective resistance will increase greatly, which is especially important for the stub. Though I believe there are "non-magnetic" steels.
Sam W.

Sam and all
I put a photo here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/138374542/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc
At 974MHz I got 4.2dB insertion loss, at 1.5GHz, I got 5.67dB insertion loss with steel stub and steel bottom metal.
Lin

Threaded connections, especially with high resistance materials, might lead to intermod distortion. When I was a child (a long time ago), I used rusty steel as a detector for a home made diode receiver. This effect might not be a problem at the low impedance end of the stub.

Scotty
ADE-11X spec does not say how much power we can apply to R and I port. You swapped the I and R as Mixer 1, in this case, if we apply 0dBm at MSA input, does this mixer work properly? The Spec does say P1dB = +1dBm.
Thanks
Lin

8913. Noise Experiment

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-13 19:05:43 UTC
From: Sam
Topic: 8913 Message: 8913

As Harold said, one experiment is worth a thousand expert opinions, so I did an experiment with an amplifier in front of my cavity filter. Just an amp, no SAW or other additional filter.

I used a 30 dB amp with 20 dB pad on the output, for a net of 10 dB gain. The amp spec says it has NF=2.3 dB. I inserted it between my diplexer output and the cavity input. I did not recalibrate, so the display levels became meaningless, so I just looked for the "minimum visible signal", which by my definition is the minimum signal that is recognizable as a distinct signal on every scan, even though its shape keeps changing due to noise. That signal previously was about -110 dBm, so I tried a level of -120 dBm. Lo and behold, there was the signal, visible on every scan, though sometimes choppy. (Note: the minimum visible signal seems to come out about 5-8 dB above the level that shows a consistent response during calibration. You can also "cheat" by zooming in to make the signal wide, which makes it more visible. When comparing with and without amp, you just have to apply the same standards both times.)

As to the high end: (I use the expanded log detector and an IF2 amp with gain of 28 dB, so others might get different results.) Up to about -10 dBm the response was very linear and then started to taper off. The change in response was still good at -5 dBm, and easily detectable but weak at 0 dBm.

Next step is to reduce the IF2 amp gain by a couple dB to make the response at 0 dBm a bit more solid. We'll see if that increases the minimum visible signal.

One downside of the amp is the possibility of IMD. But I suspect Mixer 1 is more of an IMD problem than the amp is. Still, to reduce the IMD possibilities (and maybe some spurs) I think I would at least put a low pass filter on the amp input to reduce signals at >1.5 GHz, because the LO1 harmonics are so strong. Of course, you could use a SAW as the filter, with better filtering but more loss.

In short, this works quite well.

P.S. the above was done with RBW=600 Hz. I increased the amp to 15 dB and wasn't sure whether or not there was an improvement. Reduced it to 6 dB and things got slightly worse. I then tried it with RBW=8 kHz with the 10 dB amp and got slightly better results than at 600 Hz. How well the amp works depends in part on where the noise bottleneck is in your MSA. A certain amount of narrow band noise reaches the log detector and the log detector adds a lot of wide band noise. Once you reduce the narrow band noise enough so the wide band noise dominates, further reductions accomplish nothing.

Sam W.

Lin,
I tried up to 7 dBm at the MSA input. I think my Mixer 1 has a 2.5 or 3 dB pad at its input, so this was 4-4.5 dBm at the actual mixer. I got a response of about 0.5 dBm change in output for 1 dB change in input. I'm sure the distortion was horrendous.

My objective is to get some functionality with 0 dB at the MSA input, but I don't expect a lot of precision above -5 dBm. And if you're in SA mode and worried about harmonics, -20 dBm is more reasonable.

One issue I did not test is that the mixer response probably varies over frequency at high input levels in a different way than it does at low input levels. For example, P1dB probably changes with frequency. That is one reason I wouldn't expect great precision above -5 dBm.

Sam W.

Hi Lin,
It did at one time. They have been changing their data sheets over the last few years. It is 50 mw, any port (+17 dBm), max power without damage.

With an amplifier on the output of Mixer 1, consider this. Because of "fair" mixer isolation the L port power will be about 35 dB down at the R port. +7-35=-28 dBm. With a 30 dB amplifier, this is a honking +2 dBm out of the amplifier. Not knowing your flavor of amplifier, is it in saturation?

Sam
Thanks for the infor. If we put 3dB pad at MSA input, at 0dBm input, the mixer 1 will see -3dBm. We map this signal to +15dBm at log detector. The overall MSA gain = 15dB.
As log detector responses very well at -90dBm, that means we can measure a signal well at -105dBm if the noise floor can be at -115dBm with a RBW filter. Suppose we use 1kHz RBW filter, the overall required MSA NF should be 14dB, which is a little bit hard to implement. With a calculation, we get NF=18dB. That means the noise floor is 4 dB higher than what we expected, which is -111dBm.
Therefore the dynamic range is -111dBm. We can clearly see a -105dBm signal, for a -110dBm signal, we can see it, but the SNR is almost 0.

8919. Tool To Use to Model Cavity MSA and SAW MSA

Yahoo group: spectrumanalyzer (2011)

From: nealmartini
Topic: 8919 Message: 8919

All,

There have been several discussions going on re: using the SAW-1013 filter in combination with different PADding, in addition to the cavity filter,etc. So I didn't have to keep pulling out my calculator to crank through the different scenarios, I decided to input the signal chains for the cavitiy MSA and the SAW MSA into an evaluation model. I used the the free tool from Analog Devices called ADIsimRF.

For those of you not familiar with this tool, you should take a look at it. It is as excellent way to look at the effects on noise and signal levels along a signal chain in a very structured way.

I added a file to the group file on the "1013 MHz Filter" file called MSA_ADIsimRF.docx that shows the assumptions I used and the results of a few scenarios.

http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/

The outputs I included show what happens to the signal chains as you vary the input from minimum (log detector driven) to maximum (final filter input level driven). I think I represented things accurately.

If you look at this data closely you will see that the main effect of using the SAW filter instead of the cavity filter is that the dynamic range shifts down by about 8 dB. The SAW lowers the maximum input by this same amount, but that can be handled with the use of an attenuator at the input to the MSA.

The tool is also an easy way to evaluate several of the good proposals being currently discussed by the group. The signal chain is easily modified. I hope this is of interest to some of you.

By the way, a post describing the next steps in the group buy process will be sent out tonight.

Mixer 1 noise figure may not be 7.1dB. If we do not put any noise filter at mixer 1 input, the noise at mixer 1 output will be doulbed, therefore, it is 10.1dB. But the gain is -7.1dB.
As we always add 3dB pad at MSA input, you may want to use gain=-10.1dB and NF=-13.1dB

Lin,

Good suggestion. The nice thing about having the signal chain in model form is that your suggestion is easy to insert and try.

Thanks

That is definitely a nifty tool. I don't mean to sound like an anti-mathematician, but it seems like we are very close to being able to insert the SAW module into an MSA to see what it really does. (Though I understand that Neal is not presently in a position to do this. The real world intervenes.) I think we are at the point where we will not know anything further until the new module is actually tried.

Rex, I think you said you have built one and were about to install it. If so, let us know how it works out.

I'm also curious as to what happens to the SAW profile when it has non-50-ohm input and output, which will be the case with a mixer on each end. Not that its exact profile is all that critical, but it would be nice if no unfortunate bump develops.

8925. SAW 1013 MHz Filter Group Buy Next Step

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-14 00:38:40 UTC
From: nealmartini
Topic: 8925 Message: 8925

All,

As I am sure you have observed, the group interest SAW Based 1013 MHz filter is quite high. It is now time to take the next steps in our process to make this happen. Since the requested numbers are so high, please follow the steps below to help keep the process as simple as possible so it doesn't become a part time job for me.

Here's your to do list:

1.Don't send money yet! I still am waiting for SAW quote data and shipping cost refinements. The cost for 3 SAWs and 1 PCB shipped to you should be < $18 in for US and < $21 International.

2.Please send me a direct email (nealmartini@cableone.net) with the following information:

*Your DIRECT email address.

*The number of sets of parts you want (1 set = 3 SAWs + PCB). No separate quantities of SAWs and PCBs please.

*Your group ID (name you use for posting in this group).

*Your mailing address exactly as it should appear on a mailing package (i.e. multiple lines) so I can cut and paste it without having to split up lines.

*If you are outside the US, please indicate if you would be willing to be a shipping destination for participants in your region to help simplify customs and minimize shipping costs. You will be given the $ to pay for the shipping costs.

Please send the above email by December 22nd. At that point I will have firmed up costs and will send out instructions on where to PayPal money.

Thanks for your cooperation on this!

Neal

HP appCad (http://www.hp.woodshot.com/) is also a good tool, it is free. A lot of professional RF engineers are using it.
For Noise calculation, I normally create a spreadsheet. If you know the formula, create your own calculator is not that hard.

Sam and All,
Neal sent me the SAWs yesterday. Snail mail. Darn e-mail won't deliver hardware. I'm going to go through the whole build process and document it.

That is definitely a nifty tool. I don't mean to sound like an anti-mathematician, but it seems like we are very close to being able to insert the SAW module into an MSA to see what it really does. (Though I understand that Neal is not presently in a position to do this. The real world intervenes.) I think we are at the point where we will not know anything further until the new module is actually tried.

Rex, I think you said you have built one and were about to install it. If so, let us know how it works out.

I'm also curious as to what happens to the SAW profile when it has non-50-ohm input and output, which will be the case with a mixer on each end. Not that its exact profile is all that critical, but it would be nice if no unfortunate bump develops.

Lin,

By the way, I always have a filter (Minicircuits SMA type) on my MSA input. It is either a LPF or HPF depending on which frequency band I am in. I also use a 10 dB PAD (MiniCircuits SMA type)I can remove for low level signals.

Yes, it is a single cavity, juse hold the end plate with something. If I solder the end plate on, the insertion loss could be 1.8dB.

Scotty
Thanks for the infor. For this mixer, at which power level it stops working? If I try to input a -125dBm at its input, does it still response? The output would be -132dBm, which is very low.
Thanks

Hi Lin,
I've never been asked that question, and it is a good one.
All mixers will operate down to theoretical noise floor. If the conversions loss of a mixer is -6.5 dB, then the smallest signal that can be converted is -174 + 6.5 = -167.5 dBm.
 Perhaps someone out there is using liquid helium and getting better results, but that's the best we can do at room temperature.

Hi Neal

Wouldn't it be possible to add the mmic in the SAW devices list ? Finding an ERA33 is quite impossible in Europe if you don't pass your order to Mini-Circuits UK, and I doubt they will accept selling such a device on a "per unit" basis. (without mentioning the fact that the S&H cost will be 20 Euros.. almost the cost of the Saw filter and many times the cost of the mmic itself)

And again, thank you for your time and energy.

Marc

A good working kernel is not supposed to crash unless it says "please"

Objet : [spectrumanalyzer] SAW 1013 MHz Filter Group Buy Next Step

All,

As I am sure you have observed, the group interest SAW Based 1013 MHz filter is quite high. It is now time to take the next steps in our process to make this happen. Since the requested numbers are so high, please follow the steps below to help keep the process as simple as possible so it doesn't become a part time job for me.

Here's your to do list:

1.Don't send money yet! I still am waiting for SAW quote data and shipping cost refinements. The cost for 3 SAWs and 1 PCB shipped to you should be < $18 in for US and < $21 International.

2.Please send me a direct email (nealmartini@cableone.net) with the following information:

*Your DIRECT email address.

*The number of sets of parts you want (1 set = 3 SAWs + PCB). No separate quantities of SAWs and PCBs please.

*Your group ID (name you use for posting in this group).

*Your mailing address exactly as it should appear on a mailing package (i.e. multiple lines) so I can cut and paste it without having to split up lines.

*If you are outside the US, please indicate if you would be willing to be a shipping destination for participants in your region to help simplify customs and minimize shipping costs. You will be given the $ to pay for the shipping costs.

Please send the above email by December 22nd. At that point I will have firmed up costs and will send out instructions on where to PayPal money.

Thanks for your cooperation on this!

Neal

From: Sam
Topic: 8912 Message: 8935

Lin,
Consider this: Mixer 2 presently operates with roughly 15 dB less input than Mixer 1. The MSA is operating fine with inputs of -110 dBm, which means Mixer 2 is operating fine with input of -125 dBm. Which means Mixer 1 would also operate at -125 dBm. In reality, the lower limit of usefulness is not whether the mixers produce a response, but the amount of noise that gets added later. Just a 1 kHz band of room temperature noise will produce -174+30=-144 dBm, so with Mixer 1 at -125 dBm, Mixer 2 input (-140 dBm) would almost be at the noise level, and the Mixer 2 output (-146 dBm) would be beneath the noise level.

The SA I am using can reach -140dBm with a 1 HZ RBW filter. If I get time, I would measure it.
For low power, I think the mixer should work at -167dBm like Scotty said. However, we could not directly verify it due to the equipment sensitivity. Maybe we can use a amplifier with known NF and gain and put it in front of my SA, with a 20dB gain and 3.3dB NF LNA would see this signal.
The difficulty would be how to create a -167dBm tone.
Lin

The MSA is operating fine with inputs of -110 dBm, which means Mixer 2 is operating fine with input of -125 dBm. Which means Mixer 1 would also operate at -125 dBm. In reality, the lower limit of usefulness is not whether the mixers produce a response, but the amount of noise that gets added later. Just a 1 kHz band of room temperature noise will produce -174+30=-144 dBm, so with Mixer 1 at -125 dBm, Mixer 2 input (-140 dBm) would almost be at the noise level, and the Mixer 2 output (-146 dBm) would be beneath the noise level.

Neal,

I've just been looking at the SAW filter folder to refresh my memory of parts required but I cannot see the PCB layout or values for the suggested pads.

Am I looking in the wrong place or will this info be put in the folder before we all get our soldering irons hot.

Judging by the response, you are going to be very busy in the next few weeks.

Geoff

The pads are specified as 3 dB, so take your pick:

300-18-300 ohms (3.0 dB)
270-18-270 (3.2 dB)
270-15-270 (2.9 dB)

All of these give good return loss (>30).

8939. Lin's Single cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-14 23:28:18 UTC
From: Len
Topic: 8939 Message: 8939

Hello Lin

Could you please post a photo of this device?

To the group:

As a coax size reduction attempt.

I was thinking of building a single cavity with the 2 x SMA coming out of the base plate not the sides.

With the hair pins terminating in the wall at the hole position where the SMA normally mounts.

Does the hair pin operation care which end is which? Any gurus want to shoot this idea down?

Regards

Len Spyker

All,

As I am sure you have observed, the group interest SAW Based 1013 MHz filter is quite high. It is now time to take the next steps in our process to make this happen. Since the requested numbers are so high, please follow the steps below to help keep the process as simple as possible so it doesn't become a part time job for me.

Here's your to do list:

1.Don't send money yet! I still am waiting for SAW quote data and shipping cost refinements. The cost for 3 SAWs and 1 PCB shipped to you should be < $18 in for US and < $21 International.

2.Please send me a direct email (mailto:nealmartini%40cableone.net) with the following information:

*Your DIRECT email address.

*The number of sets of parts you want (1 set = 3 SAWs + PCB). No separate quantities of SAWs and PCBs please.

*Your group ID (name you use for posting in this group).

*Your mailing address exactly as it should appear on a mailing package (i.e. multiple lines) so I can cut and paste it without having to split up lines.

*If you are outside the US, please indicate if you would be willing to be a shipping destination for participants in your region to help simplify customs and minimize shipping costs. You will be given the $ to pay for the shipping costs.

Please send the above email by December 22nd. At that point I will have firmed up costs and will send out instructions on where to PayPal money.

Thanks for your cooperation on this!

Neal

From: Sam
Topic: 8939 Message: 8943

Len,
In many of my experimental cavity filters, I had the coax coming out the base plate, and it works fine. You are just reversing the grounding connection and the in or out connection. I suppose this reverses the phase, but you do it on both input and output so even that change cancels out.

I also had the ground connection stick out the side, so I could adjust coupling by heating the connection and pulling or pushing the wire to make the loop come closer to the wall or go further away (I didn't use spacers). My main concern was whether the coax got blasted with excess heat when you solder the base plat on. That didn't seem to be a problem, though I also used fairly thin base plates so I didn't need as much heat.

It is certainly worth a try.

Len,
I should also add that I did some with the connector coming out the side, but I used a panel-mount SMA connector. If you attach a right-angle cable connector to this, you save a bit of space. Plus, you don't have the problem that if you bend and re-bend the coax connector to relocate your cavity, you don't crack the shield.

Hi Len
If the loop comes back to the be grounded at the SMA itself then you can
turn the SMA to vary the coupling.

Marc and All,
The ERA-33 for the SAW project was not chosen for its particular characteristics. We are using them elsewhere in the MSA and it seemed like a logical choice. You could replace it with a variety of other MMIC amps. It just needs to have 14 to 20 dB of gain at 1013 Mhz. You would probably have to change the two 75 ohm bias resistors for whatever replacement is used.

I appreciate your position on the ERA-33SM but we had the same problem on Sam's recent Switch buy and the approach adopted then was to supply these amps only to the international buyers but to make their purchase mandatory for all such buyers. The international price was increased accordingly. All seemed happy to do that and the group buy went well. Just a thought?

Hi Neal

Wouldn't it be possible to add the mmic in the SAW devices list ? Finding an ERA33 is quite impossible in Europe if you don't pass your order to Mini-Circuits UK, and I doubt they will accept selling such a device on a "per unit" basis. (without mentioning the fact that the S&H cost will be 20 Euros.. almost the cost of the Saw filter and many times the cost of the mmic itself)

And again, thank you for your time and energy.

Marc

All,

As I am sure you have observed, the group interest SAW Based 1013 MHz filter is quite high. It is now time to take the next steps in our process to make this happen. Since the requested numbers are so high, please follow the steps below to help keep the process as simple as possible so it doesn't become a part time job for me.

Here's your to do list:

1.Don't send money yet! I still am waiting for SAW quote data and shipping cost refinements. The cost for 3 SAWs and 1 PCB shipped to you should be < $18 in for US and < $21 International.

2.Please send me a direct email (nealmartini@...) with the following information:

*Your DIRECT email address.

*The number of sets of parts you want (1 set = 3 SAWs + PCB). No separate quantities of SAWs and PCBs please.

*Your group ID (name you use for posting in this group).

*Your mailing address exactly as it should appear on a mailing package (i.e. multiple lines) so I can cut and paste it without having to split up lines.

*If you are outside the US, please indicate if you would be willing to be a shipping destination for participants in your region to help simplify customs and minimize shipping costs. You will be given the $ to pay for the shipping costs.

Please send the above email by December 22nd. At that point I will have firmed up costs and will send out instructions on where to PayPal money.

Thanks for your cooperation on this!

Neal

Hi Marc,

This has gotten to be a very large exercise, so I had to make several simplifications to make things manageable. Additionally, several of the group members I talked to already had ERA-33SMs and did not want additional units.

MiniCircuits in the USA does accept “per unit” orders for the amplifier as well. Once again, I am sorry that I am not able to include an amplifier.

Do you still want to be on the list for the 1 set you requested?

Neal

Hi Jacques and ennio

It’s ok for me too. I have some ERA & MAR in my junkbox, but the noise factor of those are far higher than the one of the ERA33.

I’ll be ok for at leat 3 or 5 pieces (one for the SAW, two for the HF amp, and 2 for the road)

And don’t worry, Jacques, nothing is urgent right now J

Marc f6itu

Hello Jacques and all !!

Len
The single cavity structure is identical as Scotty's original cavity filter. I only changed the stub to a threaded stub and tune from bottom with a nut tight it. Later once I get more time, I will do some test to see if we can optimize the rejection and insertion loss.
Thanks
Lin

8956. SAW group buy

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-15 15:25:50 UTC
From: Sam
Topic: 8956 Message: 8956

I suggest that all further messages for Neal on the SAW group buy go directly to Neal by email, other than messages of general interest. We already have a mass of messages indicating interest; we don't need another mass providing postal addresses.

Two points on the ERA--First, per a prior posting, the LEE-39 is probably better for this purpose--lower noise, lower P1dB and higher gain. Second, maybe it would make sense for someone to do a separate group buy. Rather than people trying to find one ERA for each project, it would make sense to buy 10 and be done with it. Otherwise, the person doing the group buy will get some orders for 1, some for 5, some for 10, etc.

Sam W.

8958. RE: [spectrumanalyzer] Amplifier group buy,for SAW filter.

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-15 17:28:26 UTC
From: Staines, Stephen
Topic: 8958 Message: 8958

I would be willing to organise a group buy of ERA-33SM+ or LEE-39+. LEE-39+ is as Sam mentions probably the better option, but the package is FG873 as opposed to the ERA-33SM+ which is WW107. This may represent soldering issues for some and PCB design issues for the SAW filter board, please come back to me on this one.
My company has an account with Mini-Circuits so a small discount can be passed on. I also think that 10 should be the minimum order or multiples of 10.
Do not show your interest buy posting to the group list, I will give my direct email when a decision is made regarding the choice of Amplifier.
The cost would be parts+ tax at 20% + Jiffy bag + large letter post cost and no profit to me.
I would want payment before ordering, and will not be held responsible the any loss due to post issues. Addressing and posting will be done with the upmost care. I have taken advantage of a number of group buys from various yahoo groups so thought I should show willing.
Regards
Steve g7was.

Neal,

I've just been looking at the SAW filter folder to refresh my memory of parts required but I cannot see the PCB layout or values for the suggested pads.

Am I looking in the wrong place or will this info be put in the folder before we all get our soldering irons hot.

Judging by the response, you are going to be very busy in the next few weeks.

Geoff

Hi Steve,
The LEE series with package FG873 will fit on the current layouts using the ERA-33. For those with steady hands and good eyes, soldering should not be a problem. For others, it might be prudent to trim back the input and output trace to provide a bit more space to prevent solder bridging.
Scotty

It appears to me that the LEE package is what you would get if you embedded an ERA in a square plastic package that is slightly larger than the ERA pill shape, with the leads running to the corners of the square. The other difference is that the two ground leads are connected on the bottom of the package with a metal strip. As Scotty points out, there is a risk that the bottom strip would get soldered to the input or output pads if you don't align it perfectly, so trimming those pads is a good idea.

From: s.staines@cranfield.ac.uk
Topic: 8962 Message: 8962

If you wish to participate in the Amp group buy take note of Scotty and Sam's previous messages. Based on this info make your choice, personally I will go for the LEE amp
Send your request to this email g7wasgroupbuy @ gmail.com remove spaces around @
I would like the following info
1/ the number of lots of 10 you want. (Minimum order 10)
2/ which amp ERA or LEE, or the number of lots of each.
3/ your country of residence, so I can work out a list of postage costs.
Rough cost for 1 lot of 10 ERA amps inc package is going to be in the order of UK £17.65
Rough cost for 1 lot of 10 LEE amps inc package is going to be in the order of UK £12.10
This is base on a price break point of 100 units so as long as an order of £50 is achieved there is no delivery charge.
Postage is location dependent but UK large letter delivery is less than £1 I believe Royal mail price finder Webb page is down. Also not sure about Pay Pal charges, I think personal gift might be the method to use!
If you have any comments/suggestion or can find a cheaper source please say

8963. Re: Noise Experiment

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 8913 Message: 8963

Scotty,
I just picked up on your message. My amp seemed to function fine, and I think it handles fairly high power. I definitely got more output as I increased the input level. It's crazy to use a 30 dB amp and attenuate it down to 10 dB, but that is the only canned low noise amp I have. If I permanently implement this, I will use an amp with lower gain.

Also, some additional info. When I did the amp test, the signals seemed surprisingly noisy even with a heavy video filter. I thought maybe I was mis-remembering what the low level noise should look like, so I went ahead with the test. Today I realized that the video filter was not being automatically set, because in a software experiment a while ago I reconfigured and told the software I did not have the automatic video filter. So I configured correctly and the noise went away. I can't tell you how much time I wasted diagnosing this (suspecting Latch 4, etc.) before I realized it was a configuration problem.

With the greatly reduced noise and a 600 Hz RBW, my minimum visible signal was -115 dBm before adding the amp, and -124 dBm with the amp. And I wasn't stretching it--the -124 dBm signal was perfectly obvious on every scan when using the XNarrow filter. It came and went when using the Narrow filter.

Lin, on the question of whether the mixers operate at low level, this shows that the ADE in Mixer 1 operates at least as low as -127 dBm (-124 dBm input minus the 3 dB pad) and that Mixer 2 operates at least as low as -142 dBm. Reaching -124 dBm at the MSA input with a 600 Hz RBW is darn good when you compare it to an HP reaching -140 dBm with 1 Hz RBW.

Sam W.

> I used a 30 dB amp with 20 dB pad on the output, for a net of 10 dB gain. The amp spec says it has NF=2.3 dB. I inserted it between my diplexer output and the cavity input. I did not recalibrate, so the display levels became meaningless, so I just looked for the "minimum visible signal", which by my definition is the minimum signal that is recognizable as a distinct signal on every scan, even though its shape keeps changing due to noise. That signal previously was about -110 dBm, so I tried a level of -120 dBm. Lo and behold, there was the signal, visible on every scan, though sometimes choppy. (Note: the minimum visible signal seems to come out about 5-8 dB above the level that shows a consistent response during calibration. You can also "cheat" by zooming in to make the signal wide, which makes it more visible. When comparing with and without amp, you just have to apply the same standards both times.)
>
>
>
> As to the high end: (I use the expanded log detector and an IF2 amp with gain of 28 dB, so others might get different results.) Up to about -10 dBm the response was very linear and then started to taper off. The change in response was still good at -5 dBm, and easily detectable but weak at 0 dBm.
>
>
>
> Next step is to reduce the IF2 amp gain by a couple dB to make the response at 0 dBm a bit more solid. We'll see if that increases the minimum visible signal.

>
> One downside of the amp is the possibility of IMD. But I suspect Mixer 1 is more of an IMD problem than the amp is. Still, to reduce the IMD possibilities (and maybe some spurs) I think I would at least put a low pass filter on the amp input to reduce signals at >1.5 GHz, because the LO1 harmonics are so strong. Of course, you could use a SAW as the filter, with better filtering but more loss.
>
>
>
> In short, this works quite well.
>
>
>
> P.S. the above was done with RBW=600 Hz. I increased the amp to 15 dB and wasn't sure whether or not there was an improvement. Reduced it to 6 dB and things got slightly worse. I then tried it with RBW=8 kHz with the 10 dB amp and got slightly better results than at 600 Hz. How well the amp works depends in part on where the noise bottleneck is in your MSA. A certain amount of narrow band noise reaches the log detector and the log detector adds a lot of wide band noise. Once you reduce the narrow band noise enough so the wide band noise dominates, further reductions accomplish nothing.

8964. My 2nd cavity filter performance, 3.98dB insertion loss

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-16 05:31:34 UTC
From: inlinebeginner
Topic: 8964 Message: 8964

I just build my 2nd cavity filter, the insertion loss: 3.98dB. It is much better than my 1st one built about 1.5 years ago.
The test result is here:

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/387914832/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc

The over all rejection is here:

8968. Re: Noise Experiment

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-16 14:19:16 UTC
From: Sam
Topic: 8913 Message: 8968

Further results with my 10 dB amp in front of the cavity filter. Minimum visible signal levels (XNarrow video filter) with different RBW:

600 Hz -124 dBm
8 kHz -118 dBm
30 kHz -114 dBm
400 kHz -105 dBm

My standard for "visible" is that the signal is obvious and steady enough that you would be confident there is a signal there, even if you didn't know about the signal in advance. There is a bit of subjectivity in the test. I was being conservative, looking for very obvious signals, and could legitimately claim that the numbers are 1 or 2 dB better than shown above.

I am especially happy to be getting such good results at the wide bandwidths, which means I can see weak signals even when scanning broad frequency ranges.

From: inlinebeginner
Topic: 8964 Message: 8970

Today I measured with HP VAN, the insertion loss I got is 4.3dB. Looks like my MSA did not calibrate well above 1GHz in 1G band.
Anyway, 4.3dB is still better than 7.1dB, which is what I got on my firts cavity filter.
The interesting thing I experenced is that I disassembled this cavity filter after I first time assembled it completely. Because I saw a 20dB insertion loss. I removed the top and bottom end plates and checked hairpins, and found the center one was short to ground, due to the wrong material I used for spacers, they are melt at high temperature. I changed tje spacers and put the top and bottom end plates back, it works very well.

Topic: 8964 Message: 8971

Hi Lin and others,

Two questions come to mind.

First, my cavity filter (I've only constructed one) has 7-8dB of loss.
What is the trick to decreasing the loss from 7-8dB to the 4dB range?

Secondly, intuitively I understand that we'd like as low a loss as
possible in the cavity filter. How would a less lossy cavity filter
benefit or improve operation and use of the spectrum analyzer?

Thanks.

Steve
How did I get 4.3dB insertion loss? I did not do it on purpose. At very begining, I think 7.1dB insertion loss would be good. But the result shows that it is 4.3dB. The difference between my 1st and 2nd cavity filter are:
1) I use thiner pipe, I don't think this is the factor. I just make the weight a little bit less.
2) I use a 1.02mm wire to do the haripin. On my first filter, I used 0.9mm wire. 10% diameter increase, 21% surfce area increase. This may be the factor.
3) Clean and tight the brass screw. This would reduce about 0.3 to 0.5dB insertion loss, from what I observed. May be I am wrong.

The less insertion loss means better (smaller) noise figure, and you will have lower noise floor, and larger dynamic range.
Any reduction of attenuation before the amplifer (or the first stage of your signal chain), will help reduce the over all noise figure. That is why we want to put an amplifer for SAW replacement,the SAW chain has much larger insertion loss without the amplifer.
An ampifer in the first stage, normally can get better noise figure, but it will degrade the high power performance, we have to compromise between high and low power.

Lin

Overcouple it! 7-8 dB is normal, 4 isn't necessarily better. Usually leads to wider skirts.

Hi Steve,
Realy good question. With a well tuned filter, and not just a cavity filter, we would like the filter to be "critically coupled". That means minimal insertion loss and minimimum (designed) bandwidth and linear group delay. You can have all three, but it is very hard to achieve, especially on the home bench. We usually wind up with either of these two:
Overcoupling, which produces a wider bandwidth and less loss and crazy group delay (phase).
Undercoupling, which produces higher loss without narrowing the bandwidwidth much less than what you would get with critical coupling. Group delay suffers but not as much as when overcoupled.
If I can't get perfection, I always settle for a little undercoupling. This actually makes the filter a little easier to tune, as the elements don't interact as much as overcoupling. A little more loss is not a big deal in the MSA, where it might be in low noise reciever systems.
The hairpins are what determine the amount of coupling. Hairpins closer to the wall produces less coupled energy (undercoupling). Hairpins further from the wall produces more coupled energy (overcoupling).
You can play with the hairpins from the tops of each cavity (no top cover) until a happy medium is reached. Do this at a higher frequency. When happy with the hairpins, add the top and tune for your nominal center frequency (1013).
Our critically coupled 4 cavity filter should have 3.1 dB of insertion loss. I have been able to tune a single cavity to critical with .78 dB of loss and a bandwidth of 6.3 MHz. I have never gotten better than 4.2 dB loss with all four.
Scotty

From: marc olanié
Topic: 8975 Message: 8975

Hi Scotty

Just a line dropped to inform you that all the descriptions, building instructions and test procedure for the MSA have been translated into French.

This translation has been made by the Electrolab Team, in Nanterre (close to Paris city), with the help of a small ham radio guys. Too much hams and “hardware hackers” where interested building the MSA but were afraid to be lost with a foreign language.

http://wiki.electrolab.fr/Projets:Lab:2011:SA-Scotty

It was quite a challenge. All the work has been done in approximately 1 week

We can send you the whole contend if you need it (it’s a simple Wiki structure), for you or for Canadian MSA addicts wishing to have it.

Hope it will help to spread the “MSA Jihad” all around the world :- D

Cheers

Marc

W4ZCB
Overcoupled? Very less likely. I measured the rejection 107.2dB at 1034MHz image frequency. This shows the skirt is steepper than 1st cavity filter.
I use HP8648 provide +20dBm tone at 1034MHz, and measure the output of the cavity filter with HP8560E, RBW 10Hz, and read MKA number -91.5dBm. Therefore, the rejection at 1034MHz is +20 - (-91.5) -4.3 =107.2 dB. which is better than my 1st cavity filter 105dB rejection at 1034 MHz.

From: Sam
Topic: 8913 Message: 8978

Yes, with the switched noise filter of about 60 kHz on the narrowest two RBW, and 500 kHz on the wide ones.

One further result: I took the attenuator off the amp so I had gain of 30 dB and went through the calibration procedure (without actually changing my cal file) so I could click Measure and get the average of many measurements. I wanted to see how low I could go before two adjacent signal levels gave pretty much the same ADC readings. The readings vary a bit due to noise, so you have to do 3 or 4 Measures and average the results. I could distinguish between -142 dBm and -143 dBm, though the difference was small and not of much practical use. I didn't try any lower. This is about as far as one could expect to go with a 600 Hz RBW.

I could just leave the 30 dB amp in place and use an attenuator when I want to look at high level signals (an attenuator is nice anyway due to its improvement of input return loss and some other good effects.) Alternatively, I could use an external amp when looking at low level signals, but it is a much simpler matter to add and remove an attenuator than to do the same with an amp.

Sam W.

> > >
> > > Scotty,
> > > I just picked up on your message. My amp seemed to function fine, and I think it handles fairly high power. I definitely got more output as I increased the input level. It's crazy to use a 30 dB amp and attenuate it down to 10 dB, but that is the only canned low noise amp I have. If I permanently implement this, I will use an amp with lower gain.
> > >
> > > Also, some additional info. When I did the amp test, the signals seemed surprisingly noisy even with a heavy video filter. I thought maybe I was mis-remembering what the low level noise should look like, so I went ahead with the test. Today I realized that the video filter was not being automatically set, because in a software experiment a while ago I reconfigured and told the software I did not have the automatic video filter. So I configured correctly and the noise went away. I can't tell you how much time I wasted diagnosing this (suspecting Latch 4, etc.) before I realized it was a configuration problem.
> > >
> > > With the greatly reduced noise and a 600 Hz RBW, my minimum visible signal was -115 dBm before adding the amp, and -124 dBm with the amp. And I wasn't stretching it--the -124 dBm signal was perfectly obvious on every scan when using the XNarrow filter. It came and went when using the Narrow filter.
> > >
> > > Lin, on the question of whether the mixers operate at low level, this shows that the ADE in Mixer 1 operates at least as low as -127 dBm (-124 dBm input minus the 3 dB pad) and that Mixer 2 operates at least as low as -142 dBm. Reaching -124 dBm at the MSA input with a 600 Hz RBW is darn good when you compare it to an HP reaching -140 dBm with 1 Hz RBW.

Still, to reduce the IMD possibilities (and maybe some spurs) I think I would at least put a low pass filter on the amp input to reduce signals at >1.5 GHz, because the LO1 harmonics are so strong. Of course, you could use a SAW as the filter, with better filtering but more loss.
> > > >
> > > > In short, this works quite well.
> > > >
> > > > P.S. the above was done with RBW=600 Hz. I increased the amp to 15 dB and wasn't sure whether or not there was an improvement. Reduced it to 6 dB and things got slightly worse. I then tried it with RBW=8 kHz with the 10 dB amp and got slightly better results than at 600 Hz. How well the amp works depends in part on where the noise bottleneck is in your MSA. A certain amount of narrow band noise reaches the log detector and the log detector adds a lot of wide band noise. Once you reduce the narrow band noise enough so the wide band noise dominates, further reductions accomplish nothing.

Topic: 8964 Message: 8979

You can get a good visual idea of the effect of over and under coupling by looking at what happens if you start with low coupling and gradually increase it. With low coupling you get a nice profile with narrow bandwidth, but large loss, so the profile appears low on the screen. As you increase the coupling, the profile slides upward with virtually no change in shape. At some point it hits a soft ceiling where the peak continues to move up only a tiny bit when the rest of the profile slides up, so it starts to flatten. As you increase the coupling, the top gets smushed on the ceiling and the 3 dB bandwidth starts to widen; you are now definitely over-coupled. At this point, since the bottom of the profile keeps sliding up but the top does not, the bandwidth at any given level--say -90 dBc--gets wider and wider.

I don't know the mathematical definition of critical coupling, but I view it as the point where the peak has flattened just a bit, because until the peak starts to flatten you have nothing to lose by increasing the coupling. If you want a very flat top, you can increase the coupling a little bit beyond that.

My guess is that Lin's cavity filter is slightly beyond critical coupling (hence nice and flat and with the minimum possible loss) but not enough to cause any problems, since the rejection at +21.4 MHz is still excellent.

Sam W.

>
> Hi Steve,
> Realy good question. With a well tuned filter, and not just a cavity filter, we would like the filter to be "critically coupled". That means minimal insertion loss and minimimum (designed) bandwidth and linear group delay. You can have all three, but it is very hard to achieve, especially on the home bench. We usually wind up with either of these two:
> Overcoupling, which produces a wider bandwidth and less loss and crazy group delay (phase).
> Undercoupling, which produces higher loss without narrowing the bandwidwidth much less than what you would get with critical coupling. Group delay suffers but not as much as when overcoupled.
> Â If I can't get perfection, I always settle for a little undercoupling. This actually makes the filter a little easier to tune, as the elements don't interact as much as overcoupling. A little more loss is not a big deal in the MSA, where it might be in low noise reciever systems.
> Â The hairpins are what determine the amount of coupling. Hairpins closer to the wall produces less coupled energy (undercoupling). Hairpins further from the wall produces more coupled energy (overcoupling).
> Â You can play with the hairpins from the tops of each cavity (no top cover) until a happy medium is reached. Do this at a higher frequency. When happy with the hairpins, add the top and tune for your nominal center frequency (1013).
> Â Our critically coupled 4 cavity filter should have 3.1 dB of insertion loss. I have been able to tune a single cavity to critical with .78 dB of loss and a bandwidth of 6.3

MHz. I have never gotten better than 4.2 dB loss with all four.

Congratulations

W4ZCB

W4ZCB
Overcoupled? Very less likely. I measured the rejection 107.2dB at
1034MHz image frequency. This shows the skirt is steepper than 1st
cavity filter.
I use HP8648 provide +20dBm tone at 1034MHz, and measure the output
of the cavity filter with HP8560E, RBW 10Hz, and read MKA
number -91.5dBm. Therefore, the rejection at 1034MHz is +20 -
(-91.5) -4.3 =107.2 dB. which is better than my 1st cavity filter
105dB rejection at 1034 MHz.
Lin

Lin,
Regarding your comment on calibration. If you are trying to distinguish between 4.0 and 4.3 dB, it is absolutely critical to have an attenuator on the MSA input to make the input return loss as high as possible. This is especially true if the signal source may be very reflective. Otherwise, reflections between the MSA and the signal source can affect the measurement. (Alternatively, you could view the attenuator as part of the cavity, improving its output return loss.)

Likewise, when you do the initial calibration, your signal source must have high return loss or you must use a good attenuator.

In addition to the issue of reflections at the signal frequency, there are high frequency components that leak out the MSA input and may or may not get reflected back in, and an attenuator deals with these. I have pointed out in the past that if I measure a signal from a 50 ohm signal generator with and without a 1 GHz low pass filter, I get a 0.5 dB higher signal level with the filter, suggesting that the filter has negative insertion loss (i.e. gain). That is due to the LPF reflecting the high frequency components (mostly LO1) back in to the MSA.

It is quite easy to have a signal source that has reasonable return loss at the signal frequency, but bad return loss above 1 or 2 GHz, so the high frequency effect can catch you by surprise.

You can drive yourself crazy trying to resolve discrepancies of 0.3 dB, but a good attenuator on the MSA input can eliminate some such problems. Many commercial attenuators I have tested are not that great with regard to return loss--e.g. their DC input resistance when properly terminated might be 47 ohms. So you have to make your own or test the commercial ones. Of course, you can use the MSA to do the test.

Sam W.

Marc,

I took a look and I'm impressed. Would you mind if I shared the link at our university? We have a number of French Electronics students who might be interested.

Sam
If you can put a programable attenuator there, it would be a useful way to switch the range and sensitivity of your MSA.
Lin

>
> Yes, with the switched noise filter of about 60 kHz on the narrowest two RBW, and 500 kHz on the wide ones.
>
> One further result: I took the attenuator off the amp so I had gain of 30 dB and went through the calibration procedure (without actually changing my cal file) so I could click Measure and get the average of many measurements. I wanted to see how low I could go before two adjacent signal levels gave pretty much the same ADC readings. The readings vary a bit due to noise, so you have to do 3 or 4 Measures and average the results. I could distinguish between -142 dBm and -143 dBm, though the difference was small and not of much practical use. I didn't try any lower. This is about as far as one could expect to go with a 600 Hz RBW.
>
> I could just leave the 30 dB amp in place and use an attenuator when I want to look at high level signals (an attenuator is nice anyway due to its improvement of input return loss and some other good effects.) Alternatively, I could use an external amp when looking at low level signals, but it is a much simpler matter to add and remove an attenuator than to do the same with an amp.

It's crazy to use a 30 dB amp and attenuate it down to 10 dB, but that is the only canned low noise amp I have. If I permanently implement this, I will use an amp with lower gain.
> > > >
> > > > Also, some additional info. When I did the amp test, the signals seemed surprisingly noisy even with a heavy video filter. I thought maybe I was mis-remembering what the low level noise should look like, so I went ahead with the test. Today I realized that the video filter was not being automatically set, because in a software experiment a while ago I reconfigured and told the software I did not have the automatic video filter. So I configured correctly and the noise went away. I can't tell you how much time I wasted diagnosing this (suspecting Latch 4, etc.) before I realized it was a configuration problem.
> > > >
> > > > With the greatly reduced noise and a 600 Hz RBW, my minimum visible signal was -115 dBm before adding the amp, and -124 dBm with the amp. And I wasn't stretching it--the -124 dBm signal was perfectly obvious on every scan when using the XNarrow filter. It came and went when using the Narrow filter.
> > > >
> > > > Lin, on the question of whether the mixers operate at low level, this shows that the ADE in Mixer 1 operates at least as low as -127 dBm (-124 dBm input minus the 3 dB pad) and that Mixer 2 operates at least as low as -142 dBm. Reaching -124 dBm at the MSA input with a 600 Hz RBW is darn good when you compare it to an HP reaching -140 dBm with 1 Hz RBW.

> > > > > P.S. the above was done with RBW=600 Hz. I increased the amp to 15 dB and wasn't sure whether or not there was an improvement. Reduced it to 6 dB and things got slightly worse. I then tried it with RBW=8 kHz with the 10 dB amp and got slightly better results than at 600 Hz. How well the amp works depends in part on where the noise bottleneck is in your MSA. A certain amount of narrow band noise reaches the log detector and the log detector adds a lot of wide band noise. Once you reduce the narrow band noise enough so the wide band noise dominates, further reductions accomplish nothing.

From: inlinebeginner
Topic: 8913 Message: 8984

Here is a programmable attenuator:
http://www.triquint.com/prodserv/more_info/proddisp.aspx?prod_id=TQP4M9072

DC - 4 GHz
0.5 dB LSB Steps to 31.5dB
+57 dBm Input IP3
1.6 dB Insertion Loss @ 2 GHz
TTL / CMOS Compatible Serial Control Interface
No requirement for external bypass capacitors for operation above 700 MHz
50 O Impedance
+5V Supply Voltage
4x4mm QFN package

After we add this attenuator, we may need to design an auto calibration routine. Because the cases will be increased rapidly, considering all the RBW combinations.

Lin

> >
> > Yes, with the switched noise filter of about 60 kHz on the narrowest two RBW, and 500 kHz on the wide ones.
> >
> > One further result: I took the attenuator off the amp so I had gain of 30 dB and went through the calibration procedure (without actually changing my cal file) so I could click Measure and get the average of many measurements. I wanted to see how low I could go before two adjacent signal levels gave pretty much the same ADC readings. The readings vary a bit due to noise, so you have to do 3 or 4 Measures and average the results. I could distinguish between -142 dBm and -143 dBm, though the difference was small and not of much practical use. I didn't try any lower. This is about as far as one could expect to go with a 600 Hz RBW.
> >
> > I could just leave the 30 dB amp in place and use an attenuator when I want to look at high level signals (an attenuator is nice anyway due to its improvement of input return loss and some other good effects.) Alternatively, I could use an external amp when looking at low level signals, but it is a much simpler matter to add and remove an attenuator than to do the same with an amp.

> > > > > I just picked up on your message. My amp seemed to function fine, and I think it handles fairly high power. I definitely got more output as I increased the input level. It's crazy to use a 30 dB amp and attenuate it down to 10 dB, but that is the only canned low noise amp I have. If I permanently implement this, I will use an amp with lower gain.
> > > > >
> > > > > Also, some additional info. When I did the amp test, the signals seemed surprisingly noisy even with a heavy video filter. I thought maybe I was mis-remembering what the low level noise should look like, so I went ahead with the test. Today I realized that the video filter was not being automatically set, because in a software experiment a while ago I reconfigured and told the software I did not have the automatic video filter. So I configured correctly and the noise went away. I can't tell you how much time I wasted diagnosing this (suspecting Latch 4, etc.) before I realized it was a configuration problem.
> > > > >
> > > > > With the greatly reduced noise and a 600 Hz RBW, my minimum visible signal was -115 dBm before adding the amp, and -124 dBm with the amp. And I wasn't stretching it--the -124 dBm signal was perfectly obvious on every scan when using the XNarrow filter. It came and went when using the Narrow filter.
> > > > >
> > > > > Lin, on the question of whether the mixers operate at low level, this shows that

the ADE in Mixer 1 operates at least as low as -127 dBm (-124 dBm input minus the 3 dB pad) and that Mixer 2 operates at least as low as -142 dBm. Reaching -124 dBm at the MSA input with a 600 Hz RBW is darn good when you compare it to an HP reaching -140 dBm with 1 Hz RBW.

8986. Amp Group buy update

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-16 22:31:53 UTC
From: s.staines@cranfield.ac.uk
Topic: 8986 Message: 8986

Group buy is jogging along, well passed the £50 point, so no delivery charge to me, therefore the buy will go ahead.

Send your request to this email g7wasgroupbuy @ gmail.com remove spaces around @
I would like the following info
1/ the number of lots of 10 you want. (Minimum order 10)
2/ which amp ERA or LEE, or the number of lots of each.
3/ your country of residence, so I can work out a list of postage costs.
Rough cost for 1 lot of 10 ERA amps inc package is going to be in the order of UK £17.65
Rough cost for 1 lot of 10 LEE amps inc package is going to be in the order of UK £12.10

Royal mail price finder Webb page still down.

If you have any comments/suggestion or can find a cheaper source please say. Is the minimum order of 10 Okay.
Steve g7was.

8987. Re: Noise Experiment

Lin,
That's an impressive device. But for myself, I find it a simple matter to add/remove attenuators, and I don't have much use for attenuation in small steps, so it wouldn't be worth the trouble.

I did find an interesting technique in their data sheet. The evaluation board has SMA end-launch connectors, and the center pins have a 0.2 pF capacitors to ground "to resonate out the inductance of the connector." Interesting idea, though they use thin PCB where via inductance is small; a different value might be needed on 0.060" boards.

Sam W.

8988. Re: Cavity filter test results

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-16 22:45:26 UTC
From: neganur
Topic: 8694 Message: 8988

I meant to post my results earlier but got caught up in work.

My filter is finished and the results are:

Centre frequency: 1013.3 MHz

Insertion loss: -8.57 dB

Bandwidth(3 dB): 1.10 MHz
Bandwidth(6 dB): not tested
Bandwidth(30 dB): 3.25 MHz
Bandwidth(60 dB): 7.76 MHz

Rejection(1024 MHz): -104 dB
Rejection(1034.7 MHz): -114 dB

The entire filter is made of copper. I used 0.2" flat bar for the top an bottom plates.

The thick copper bars have almost been a show-stopper for me since it was impossible to drill holes for the hair pin couplers. Luckily, Sam recommended me to not drill holes at all and rather notch the tube and bend the hair pin through the notch. This worked very well.

I used a hot air gun to solder the tubes together and got very nice joints using this method. The tubes were then placed on top of the bottom plate. I placing a ring of solder wire on the inside of each cavity while and simply fed solder to the outside joints as the bottom plate was hot enough to melt it. Lots of flux and the result was excellent.

The annoying part began when I wanted to attach the top plate next evening. Since everything is made out of copper, the tubes were conducting the heat so well - the bottom joints were melting (meaning solder running down inside the cavities). I had to remove a lot of excess solder and redo the bottom joints once the metal cooled.

I also noticed that some of the holes that interconnect the cavities had lost solder and were not RF tight. How did other people solve this? I wonder if I should just leave a short piece of the 0.141" copper mantle on the hair pin instead of using just the Teflon.

Looking back, it was really much harder to gather all the material than the soldering. Hardware stores here suck.

All the drilling was done with a cheap hand drill. I hated every minute of it! Our workshop has a drill press, unfortunately I didn't get access to it.

There are a couple of pictures of the filter and transmission plots in my photo album:

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/910808747/pic/list

Thanks again Sam, the hint regarding the couplers helped me to finish this!

Best regards
Chris

Lin,

I was looking at something similar with an Hittite HMC424LP3 (6-bit 0.5 dB LSB 31.5 dB DC-13 GHz)

http://www.hittite.com/content/documents/data_sheet/hmc424lp3.pdf

Your device has a better insertion loss, though.

Chris

Topic: 8694 Message: 8990

Nice, clean job of construction. When you soldered the top, it might have helped to wrap a wet rag around the bottom half to avoid melting the bottom (or maybe stand it in a pan of water). I would think you could apply some solder near any leaking holes and the solder would pool in that area. Maybe using low-temp solder might help for that limited purpose (Chip-Quik's "SMDLTFP"?)

Per the recent discussion of coupling, yours is likely a bit undercoupled, accounting for the slightly high insertion loss and very narrow bandwidth. But that's probably no big deal. In fact, following on my idea of using an amp in front of the cavity filter, I'm not sure the insertion loss of the filter has much significance at all. If your filter has somewhat high loss, just use a few more dB of amp gain.

Sam W.

From: Sam
Topic: 3452 Message: 8991

I have a question regarding project enclosures (not necessarily relevant to the main MSA enclosure). I have noticed that projects built by Europeans frequently are built in tin-plate enclosures, which seem pretty convenient and easy to drill/cut for connectors, etc. US projects seem never to be in such enclosures. Some time ago, I searched for sources of tin-plate enclosures, and found just a couple, all in Europe.

What's up with tin-plate?

Sam W.

There are several reasons, among others years ago aluminum was difficult to get in Europe and there were no cast, extruded or preformed boxes. All radio chassis were always tin plate and, when a teenager, I built an oscilloscope with tin plate subassemblies..

A more esoteric reason is that, since tin plate is tin coated steel, it insulates the insides from magnetic fields.

I found a roll of K&S .005" soft brass, 12" x 30" recently at a Hobby Lobby store. (Bought it) They also had small pieces of tin plate. I did not find any way to order this roll of brass material online from them. They do have a lot of other materials
The stock number of the K&S brass roll is 6010. Googling that, I found that Tower Hobbies carries the roll of brass, tin plate sheets, and most of the K&S line. Both the brass and tin plate are also at Grainger, Ebay, and Amazon. Amazon had the best price. I just searched for the stock number I had (K&S 6010), and then looked at the other K&S items the dealer had. (Phils Hobby Shop, selling through an Amazon storefront, has most of the K&S line)

Hi guys,

Nice French translation done, guess it was not really a piece of cake doing this in only one week.
I feel more comfortable to know there's now a French site which explains in details Scotty's MSA building, and over this all the options and details needed to have it operationnel.
Just to say in fact that it's always a little bit easier when using one's native language even if fluent in English.

8995. Cavity Question

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-17 14:42:38 UTC
From: allenkeehall
Topic: 8975 Message: 8995

I've been finding the discussions on the cavity filter very interesting and have some questions for those who've extensively built and toyed with them. I was considering building my first one with adjusting brass rods as opposed to copper tubing inner conductors and screws. I ordered the 1/4" brass but now I'm having a few doubts since copper is undoubtedly a better conductor.

Would it be be better to plug flat the ends of the inner tube copper conductors? Could this result in easier or better tuning response from the screws?

The fact that the screws center in a null of sorts (hole in the inner copper tubing) wouldn't this be detrimental to the desired effects via fringing?

BTW, based on the results going back and forth I believe implementing the SAW is now a no brainer. Very impressive work!

Thanks in advance for your thoughts.

My local hobby store stocks a lot of K&S products, but I never thought of looking there for tin plate. Ideally, I was hoping to locate an actual tin-plate chassis.

On the K&S topic, I have mentioned in the past that I use their brass for fencing and lids, but my stash of brass is unlabeled so I never know the actual thicknesses to recommend. I recently bought 0.01" sheet so I would have some of known thickness. It works great for fencing and I would not want anything thicker. Your 0.005" sheet should work well too. In fact, it is ideal to make the lids of very thin flexible brass because it makes them much easier to remove--if you heat a corner you can bend it up to release it and move on to the next area.

Pre-made brass strips don't seem to be made of anything thinner than 0.015" material, which is workable but too thick for my taste. I cut strips out of thinner sheet, which can be done with a scissors or paper cutter.

Topic: 8975 Message: 8997

You are correct that copper will do better than brass as the center conductor, which is the place where resistance is most critical. I'm not sure it makes much difference for the outer tube or end plates.

Copper will make a little less difference than you might think. Even though it has lower resistivity than brass, the skin depth is proportional to the square root of resistivity. Net effect, if you double the resistivity the actual resistance goes up by only 40%. So a brass center rod will give somewhat worse performance, but I think it will make a perfectly useable filter.

Plugging the inner tube will probably increase the amount of capacitance created by the screw at any given setting, but won't improve performance. Fancy filters sometimes have solid rods with a hole drilled into the end so the screw can actually extend inside the rod, allowing for more capacitance and greater tuning range. (Sounds like an alignment nightmare and we don't need much range.)

Very impressive, up to 13GHz.
I think many company provide similar attenuators. The reason that I showed you TriQuint part is that TriQuint FE sent me an eval board a while ago, to see if I could use it in some project.

Neal and Scotty,

1. Did you find it necessary to cut the SAW module into two parts to get good isolation, or was it just a matter of making room for connectors?

2. The filter response seems to peak a bit above 1013.3 MHz, and appears to be broad enough that you could specify LO2=1028 MHz, putting the nominal filter at 1017.3 MHz, in which case the image at +21.4 MHz would be completely obliterated. Good idea?

3. The fencing over the SAW appears to be actually soldered to the SAW module. True?

9000. SAW Amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-17 21:35:35 UTC
From: Sam
Topic: 9000 Message: 9000

I checked the output of my diplexer to see what the max power level would be. I got -11 dBm with the MSA input power to the point where another 1 dB of input increased the diplexer output by only 0.1 dB. This took something like 10 dBm at the MSA input. So I would conclude the most it would ever be is -10 dBm. I think my Mixer 1 has relatively high loss (maybe 8 dBm) and maybe the diplexer adds a dB of loss, so maybe others could get a bit more power, such as -7 dBm.

If you fed this -7 dBm to the SAW module, there would be another 6 dB loss before the amp, yielding -13 dBm at the amp, so even with 21 dB gain in the amp the power to the subsequent SAW would only be +8 dBm. It therefore appears to me that Mixer 1 provides the needed limiting to protect the SAW from excessive power whether you use the ERA or the LEE amp. If you already have the ERA-33sm it would reasonable to use it. Otherwise the LEE-39 is still slightly better.

Sam,

1. Did you find it necessary to cut the SAW module into two parts to get good isolation, or was it just a matter of making room for connectors?
The shield over the center of the SAW is there for input to output isolation. This is mainly a “through the air” barrier. Additionally, if you look under the SAW on the PCB, there is a ground barrier between the SAW’s input and output pads. There are a few closely spaced vias in this barrier. Scotty wanted these there to help prevent internal FR4 path leakage. Incidentally, the reduction of the leakage improved dramatically when just this shield was installed (without any side or top shielding).

2. The filter response seems to peak a bit above 1013.3 MHz, and appears to be broad enough that you could specify LO2=1028 MHz, putting the nominal filter at 1017.3 MHz, in which case the image at +21.4 MHz would be completely obliterated. Good idea?
The peak of the response occurs at about 1014.7 MHz (similar to the SAW’s data sheet plot). The response is definitely broad enough to shift LO2 as you suggest. It is not clear how much additional rejection at the image frequency this would buy you. Using my MSA with its noise floor, I can’t tell if the ultimate rejection is being determined by the noise floor or if the filter actually has more rejection to offer.

3. The fencing over the SAW appears to be actually soldered to the SAW module. True?
I didn’t actually touch my soldering iron directly to the SAW for fear of destroying one of the few SAWs I had. What I did was used a very hot soldering iron and heated the shield above the SAW and let the solder flow down to the SAW. Scotty is assembling one of these as we speak and I think he intends to try/describe how this shield should be installed.

Neal,
What I was thinking of regarding the module being cut in half is whether you could leave it as one piece and put a fence along the line that otherwise would be cut (probably a double-sided PCB fence). The connectors would be cramped, but if you used direct-soldered-coax to connect the amp output to the input of the dual-SAW section, you would only need two SMAs so there would be room.

Sam,

Sorry, I misunderstood what you were asking. You'd have to try what your suggesting and see how effective it is. I am sure you noticed that there are not the usual number of vias on the boundary traces that other SLIMs have. There are very few on that edge of the AMP SAW board. This was done to keep the number of holes/board below the 350 required for an ExpressPCB mini board. This is not a problem when you cut the board first because you can solder the shield to the top and bottom of the PCB. I don't know if this would be a problem for what your suggesting.

Hi Sam and All,
1. The sections must be cut apart so that full perimeter fencing can be used on each section. This is needed to minimize crosstalk between sections.
2. So true, PLO 2 can be run at 1028 MHz with no problem.
3. Yes, the internal fence does have a solder fillet connecting the top of the SAW. It accepts solder nicely.

I am updating the web page to include my test results while building up the SAW sections. The first part, dual SAW section should be finished later tonight, assuming the Cowboys are as depressing as they have been.

Neal and Scotty,

1. Did you find it necessary to cut the SAW module into two parts to get good isolation, or was it just a matter of making room for connectors?

2. The filter response seems to peak a bit above 1013.3 MHz, and appears to be broad enough that you could specify LO2=1028 MHz, putting the nominal filter at 1017.3 MHz, in which case the image at +21.4 MHz would be completely obliterated. Good idea?

3. The fencing over the SAW appears to be actually soldered to the SAW module. True?

From: Len
Topic: 9005 Message: 9005

Hello Group

At the moment I am building MSA coax filters serial numbers 31 to 45, including 3 kits

From the official Wiki Leaks:

>>>>>>>>>>>>>>>

(1) Top and bottom plates are 1mm copper or 25 thou or 1/40" or gauge xxx

The pipes are so stiff a thinner "flexible" top and base plate is actually good not bad.

(2) The first soldering/brazing step is to use plumber's Silver 15% rods to braze the 4 tubes together.

Of course the Pipes are already machined to size with hairpin loop holes in them .

Brazing temperature is well over >> 1000F, >>700C with a MAPGAS flame.

(3) There is a jig for clamping them all together while this happens.

A single steel rod through all the hairpin holes lines all the pipes up nicely and keeps the holes open.

(4) The copper is now all black, clean them by soaking them alternatively in Vinegar and or de-scaling agent.

Then polish them back up with emery cloth wet and dry sanding paper.

The brazing exercise is the key.

The pipe assembly is now proof against excess soldering heat and other timing disasters.

Further soldering on the bottom, top, sides can never ever loosen the pipes or expose the coupling holes!!

>>>>>>>>>>>

Happy to sell just the 4 machined pipes brazed together with all hairpin loops holes and polished.

Price U$ 28 plus approx U$ 20 post from Perth Australia to the rest of the world.

The post cost is high, Perth WA is roughly on the opposite side of the world to New York.

See also my photos and kit instruction notes in my group files or e-mail me and I will send it.

Regards

Len Spyker

Hi All,
I have just updated the SAW web page:
http://scottyspectrumanalyzer.com/slim_sfa_1013.html

I added a section at the bottom of the page called:
Test, Evaluation, and Characterization
It is basically notes and pictures and graphs as I build and evaluate the module. The only surprise I got was how small the SAW is. The data I have taken is very close to Neal's.

Objet : [spectrumanalyzer] Re: Enclosures

My local hobby store stocks a lot of K&S products, but I never thought of looking there for tin plate. Ideally, I was hoping to locate an actual tin-plate chassis.

On the K&S topic, I have mentioned in the past that I use their brass for fencing and lids, but my stash of brass is unlabeled so I never know the actual thicknesses to recommend. I recently bought 0.01" sheet so I would have some of known thickness. It works great for fencing and I would not want anything thicker. Your 0.005" sheet should work well too. In fact, it is ideal to make the lids of very thin flexible brass because it makes them much easier to remove--if you heat a corner you can bend it up to release it and move on to the next area.

Pre-made brass strips don't seem to be made of anything thinner than 0.015" material, which is workable but too thick for my taste. I cut strips out of thinner sheet, which can be done with a scissors or paper cutter.

From: Steve
Topic: 9008 Message: 9008

Scotty,

The *Construction Techniques* *Using SLIMs *web page has a sentence which reads "When completed, wash and clean the board with isopropyl alcohol (90 % or better)."

How does one do the cleaning? Scrub with a toothbrush? Immerse and slosh in IPA? Pressure wash with IPA? Other?

Is there anything to observe to indicate the PWB is acceptably clean?

I have noticed that IPA (90% is all I can find in this area) seems to "melt" the edges of the PWB a little. To the extent that the edges are sticky for a while. They seem to eventually "dry" and harden and are no longer sticky. Have you noticed that?

Thanks.

One thing I've noticed recently is that the solder flux is still in suspension in the alcohol. It's important to remove it as best as you can. I use an air duster or compressed air to blow the fluid off. Otherwise, when the alcohol evaporates, the flux will be re-deposited on the board and it feels quite sticky. Also, I've seen that someone suggested using an ultrasonic jewelry cleaner with the alcohol.

Yes, agreed, a single alcohol solution leaves a lot of residual flux.

My vote is to do a four step cleaning finishing with water. First step is alcohol second step is aqueous saponifier third step is tap water, fourth step is deionized water. Simpler method is a first step of alcohol followed by a second step of fresh alcohol to dilute and remove residuals from the first wash followed by water with dishwashing liquid. Saponifier is a water soluble solution (I believe that it is similar to lye) that is added to hot water (I used a hot plate with a pyrex glass cooking pan on the plate) the saponifier is very aggressive to solder fluxes. You will need gloves. It will burn holes in your clothing. Only a capful of the stuff goes in a quart of water. Finish cleaning in water with dishwashing liquid followed by water followed by DI water if desired.

Hi Steve,
 You could use a toothbrush but it too large. Go to the hardware store, plumber's section and ask for "acid brushes". Also called "flux brush". Used to apply flux to copper tubing before soldering. They are cheap, about 20 cents. Get several. The bristles are about 1 inch long. Cut them back to 1/2 inch, making the brush stiffer.

You are not experiencing "melting". If it is sticky, that is the flux.

Here is the best method for cleaning.
Lay out 3 small containers to hold the alcohol. I use the little plastic containers that hold the icing in the cinnamon rolls. About a teaspoon in the first. Just a few drops in the other two. Use 3 acid brushes, one for each. This prevents cross contamination.
1. Use enough alcohol from the first to well saturate the components. Drown them. Let the unit sit for a minute to let the flux soften. Then scrub. Use a paper towel to absorb the "wash". Repeat twice.
2. Use brush 2 and container 2 and scrub again. Use clean area of paper towel to blot up the "wash".
3. Use brush 3 and container 3 and scrub again. Use clean area of paper towel to blot up the "wash".
Let the unit dry naturally. You can "fan" it, but do not blow on it. After drying hold unit and look for "stains", "rings" around components, etc. If you see anything, it is not clean. Visual inspection under components is impossible, but if there is any flux under them, the "rings" are a giveaway.

Also, go to your pharmacist and ask for "pure" isopropyl. He may direct you to 99 or 100 %. I get my 99% at Kroger (aka Safeway or Piggly Wiggly).

I use absolutely no other chemicals.

I use a similar procedure. A toothbrush has worked fine for me but the flux brushes probably have finer bristles. The flux brushes are also sold in hobby stores in packages of 10 or so for general purpose use; they are just a metal tube crimped onto the bristles. Whatever brush you use, it is important to wiggle it as you move around to work it into small spaces. If you just brush back and forth, there will be "shadow" areas next to every component, where the brush didn't reach.

The blotting step is also critical, because if you just let the excess alcohol dry, everything dissolved in it will just redeposit. I'm also paranoid about static, so don't rub with the paper towel (which will also rip pieces off it); just dab. I also do it at my laundry sink where I can periodically touch the spigot to get grounded.

For each step I just pour alcohol from the bottle and let some run off the board. A bit more wasteful, perhaps. For the third step, I don't use the brush; I just pour on extra alcohol.

90% alcohol is readily available (Target) and works well. 70% is even more common but you don't want that if you have a choice. I've never seen 100%.

Scotty (and others),

Thanks for the advice. I've have been cleaning my PWB's with a toothbrush and 90% isopropyl alcohol, but not as rigorously as you guys describe. My new year's resolution is to do better :-)

By way of background (and perhaps motivation), what is the reason for such thorough cleaning? What are the consequences of not cleaning the board at all or of doing a less than stellar job?

Greg,
Sounds a bit too heavy duty. However, it might be a great idea for cleaning the cavity filter. I used plumber's solder and that flux is very hard to clean off. Perhaps "saponifier" (a/k/a lye, Drano and garage degreaser fluid) would be perfect for that.

From: Sam
Topic: 9008 Message: 9015

In most cases, it is purely cosmetic, but in some cases it may prevent corrosion. And in some cases the flux is slightly conductive and causes problems--especially a problem for PLL's. In fact, on my PLL control loop components I did an extra cleaning with acetone, though I did not notice a difference.

There is a type of flux called "No Clean" which is supposedly non-conductive so you don't have to clean it off. But it still leaves a residue so I clean it anyway.

Finally, if you solder with solder paste and hot air, it is not uncommon to get a number of tiny solder balls stuck in flux, which have the potential to cause trouble, and the scrubbing removes them.

Also, some fluxes are very slightly conductive. By throughly cleaning it off you can ensure that you're not getting additional leakage from the solder flux.

On Dec 18, 2011, at 4:25 AM, Greg Broburg wrote:

> Yes, agreed, a single alcohol solution leaves a lot of residual flux.
>
> My vote is to do a four step cleaning finishing with water. First step is alcohol second step is aqueous saponifier third step is tap water, fourth step is deionized water. Simpler method is a first step of alcohol followed by a second step of fresh alcohol to dilute and remove residuals from the first wash followed by water with dishwashing liquid. Saponifier is a water soluble solution (I believe that it is similar to lye) that is added to hot water (I used a hot plate with a pyrex glass cooking pan on the plate) the saponifier is very aggressive to solder fluxes. You will need gloves. It will burn holes in your clothing. Only a capful of the stuff goes in a quart of water. Finish cleaning in water with dishwashing liquid followed by water followed by DI water if desired.

I use an air duster or compressed air to blow the fluid off. Otherwise, when the alcohol evaporates, the flux will be re-deposited on the board and it feels quite sticky. Also, I've seen that someone suggested using an ultrasonic jewelry cleaner with the alcohol.

> Sam W.

For the cavity filters, you might use a technique we use when silver soldering large (6" and 8") TV broadcast transmission lines.

After silver soldering, we use Naval Jelly to break down the flux and corroded copper, ScotchBrite pads and emery cloth to scrub everything clean, and then rinse with a baking soda solution to neutralize the acidic Naval Jelly, finally rinsing and wiping down everything with clean water.

9018. Pre-Cavity Amp

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 9018 Message: 9018

I have now actually installed an amp in front of my cavity filter (ERA-33 attenuated down to 7 dB gain). I'm guessing the performance of this with the cavity filter will be similar to the performance of the SAW module with its internal amp.

I recalibrated, though my calibration is not extremely precise because I did it with my MSA upside down with the bottom off and the fan not running, so it was never at thermal equilibrium.

My minimum visible signal with 600 kHz RBW is -122 dBm. My goal was to get a stable signal at -120 dBm. Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

On the high end, I was aiming for useable but not great response at 0 dBm. I get very strong response at -5 dBm and decent response at 0 dBm, and was able to calibrate to 6 dBm with the ADC values still increasing a useful amount.

This is all in my 600 Hz RBW path. For wider paths, I lose a couple dB at the high end and varying amounts on the low end.

In summary, I have a solid response from -120 dBm to 0 dBm, with at least 5 dB of lesser response added on to each end.

Sam W.

About cleaning cavity filters:

I built a few cavity filters, 2, 4, and 5 cavity types with a variety of tuning methods as experiments. I also used silver brazing rod to hold the tubes together permanently, as Len did in his production run. The high heat heavily oxidized the inside of the tube. After slicing and blistering my fingers trying to polish the inside by hand, I made a tool. A scrap of steel rod about 0.18"diam, folded and hammered flat, with about 0.15" clearance between the folded portion. The folded length is about 7" long. I ground a chisel point onto the end of a small bolt (1/4" diam) , cut the bolt head off, and welded the chiseled end into the open end of the folded rod.
The bolt goes into a drill chuck. A sheet of Scotchbrite goes into the slot, centered. Insert tool into the tube and polish. It worked but wore out the Scotchbrite quickly. Next try was wrapping a sheet of sandpaper with the Scotchbrite, with the sandpaper exposed, doing the abrasion. Works great. Finish with finer sandpaper, and then with just the Scotchbrite.
My materials and dimensions were purely arbitrary, and were whatever was in my garage. This method could probably be done with just a doubled wire in a hand drill. Use low speed to avoid vibration.
Jerry

From: inlinebeginner
Topic: 8964 Message: 9020

I just created three more cavity filters, the performance is almost identical. 4.3dB insertion loss. The photo is here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/2050934276/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc

One test I did is that how important the inner surface cleaning. The one I did not clean the top plate, bottom plate and the center stubs got about 0.3dB more insertion loss, with a little bit narrow BW. I think the surface cleaning may not that important, the 0.3dB degradation may come from the under-coupling, according to the measured BW number.
Lin

--- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@...> wrote:
>
> Lin,
> Regarding your comment on calibration. If you are trying to distinguish between 4.0 and 4.3 dB, it is absolutely critical to have an attenuator on the MSA input to make the input return loss as high as possible. This is especially true if the signal source may be very reflective. Otherwise, reflections between the MSA and the signal source can affect the measurement. (Alternatively, you could view the attenuator as part of the cavity, improving its output return loss.)
>
> Likewise, when you do the initial calibration, your signal source must have high return loss or you must use a good attenuator.
>
> In addition to the issue of reflections at the signal frequency, there are high frequency components that leak out the MSA input and may or may not get reflected back in, and an attenuator deals with these. I have pointed out in the past that if I measure a signal from a 50 ohm signal generator with and without a 1 GHz low pass filter, I get a 0.5 dB higher signal level with the filter, suggesting that the filter has negative insertion loss (i.e. gain). That is due to the LPF reflecting the high frequency components (mostly LO1) back in to the MSA.
>
> It is quite easy to have a signal source that has reasonable return loss at the signal frequency, but bad return loss above 1 or 2 GHz, so the high frequency effect can catch you by surprise.
>
> You can drive yourself crazy trying to resolve discrepancies of 0.3 dB, but a good attenuator on the MSA input can eliminate some such problems. Many commercial attenuators I have tested are not that great with regard to return loss--e.g. their DC input resistance when properly terminated might be 47 ohms. So you have to make your own or test the commercial ones. Of course, you can use the MSA to do the test.

> > Anyway, 4.3dB is still better than 7.1dB, which is what I got on my firts cavity filter.
> > The interesting thing I experenced is that I disassembled this cavity filter after I first time assembled it completely. Because I saw a 20dB insertion loss. I removed the top and bottom end plates and checked hairpins, and found the center one was short to ground, due to the wrong material I used for spacers, they are melt at high temperature. I changed tje spacers and put the top and bottom end plates back, it works very well.

Sam
This is achieved only with your expended log detector. If someone use Scotty's original IFA1+IFA2 and a 1kHz RBW filter, it may not reach -120dBm.

If we can find a VGA working at 1013.3MHz, we might be able to apply the similar concept of the expended log detector on cavity filter amplifier. i.e. the gain is controlled with the log detector output, at hihger power input, the gain dropes more and at lower power the gain increases more. In this way, we can have larger dynamic range. The overall is a IF amplifer at 1013.3MHz but the BW is determined by the RBW filters.

Calibration may not be a problem, because what we see from high RF VGA input is a log detector with larger dynamic range. Therefore, the calibration would be the same as is.

Lin,
A fundamental limitation of the VGA+log detector concept is that you can't allow signals to reach the VGA unless they will also reach the log detector. Otherwise, a strong signal can overload the VGA without the log detector knowing about it. That is the reason I use the arrangement RBW Filters->VGA->Noise Filter->log detector, with the Noise Filter always broader bandwidth than the RBW filter.

You actually could violate this rule for VNA use only, as long as there would never be a spurious signal strong enough to overload the VGA. That might be the case with a VGA located after the cavity filter (maybe even before the cavity) as long as the VGA never had gain greater than 30 dB or so. (The prime overload risk would come from leaked LO1.)

The cavity filter response is not changed by this arrangement, so if you have 100 dBc rejection at +21.4 MHz, and are viewing a signal of -20 dBm, you will see a -120 dBm ghost image. Reducing the minimum visible signal doesn't worsen the image, but makes it easier to see the image. With a -20 dBm signal you may also be creating low level harmonics, that also might become more visible with increased dynamic range.

When you reduce the low end, you will be able to see more, and some of what you see might be stuff you don't want to see.

Lin,
Actually, you can let signals get to the VGA but not the log detector as long as the max gain of the VGA won't allow it to be overloaded by such stray signals. One way to make use of this would be to put a second VGA in front of the RBW filters. The IF2 amp might still be required, but with reduced gain--just enough to keep the noise level down. The second VGA could tie into the same control line as the first, and would have to have its gain limited to 20 dB or so to avoid the possibility of overload.

You could do the same thing at the cavity filter, but finding a reasonably low noise VGA that operates at >1 GHz, and has enough range not to be overloaded, may be a challenge.

Sam
This is what I was calculating this morning. Here is what I got:
The MSA could have range: 0 dBm to -120dBm, with the following VGA config:

For 0dBm input: 3dB pad+ mixer1+ VGA1=10dB + cavity + mixer 2+ VGA2 =0dB + IFA2 + RBW. The log detector will see power around 0dBm.
For -120 dBm input: VGA1= 20dB, and VGA2=20dB.

To not overload the VGA1, we may put noise filter in front of VGA1 (worst case we can put two cavity filters).

The VGA may not be a real VGA, it could be a ERA-33+ Voltage controlled attenuator, if we can find one.

If we extend this concept, we can put a voltage controlled attenuator at Mixer1 input. That would extend the dynamic range to +20dBm to -120dBm.

Lin

Topic: 9018 Message: 9030

Lin,
I'm getting -120 dBm to 0 dBm now, with a fixed 7 dB amp rather than your VGA1.

If you have a regular need to view lower signals, I think the way to go is to increase the amp gain and use a "manually-controlled attenuator"--i.e insert one when necessary to see high level signals.
If you rarely need the low levels, you can leave the internal amp at 7 dB, or even leave it out, but add an external amp when necessary.

There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.

Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.

One might even say that the pre-cavity amp is not all that necessary. I was just compulsive about getting a solid -120 to 0 dB range. Plus, I wanted to get an idea what type of range I would get with the SAW module, which I expect will come out in the ballpark of what I get with the pre-cavity amp.

Sam W.

Sam
My calculation is very conservitive. The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

9032. Re: Pre-Cavity Amp

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 9018 Message: 9032

It can all work as long as you don't overload anything along the way. A VGA immediately before or after the cavity filter would have to be able to handle inputs of at least -15 or -20 dBm along with the desired signal without becoming saturated in order to work well in SA mode. And have low noise. As a practical matter, I suspect you would need a small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA noise.

The expanded log detector was intended to be linear-in-db over as broad a range as possible, but because of our path calibration this linearity is not actually critical for the MSA. Any voltage-controlled mechanism would work that has high gain at low inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to require calibration at fine intervals. If would even be fine for the gain to hit its minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode attenuator could work, if it has reasonable temperature stability.

> My calculation is very conservitive. The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

leave it out, but add an external amp when necessary.
> >
> > There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> >
> > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.
> >

That is more than shifting the sensitivity range, looks to me you are expanding the range?!
In my testing the Expanded Lg Amp by itself could only get from -3 to -105.

From: inlinebeginner
Topic: 9018 Message: 9034

Jurgen
With a fixed gain amplifier, we can only shift the log detector range up and down, but we can not expend the range.
With VGA, we can not only shift the log detector range, but also expend the range. The reason it can expend the range is that it provides a variable gain according to the log detector output nearlly linearly. At lowe input power end, it provide max gain, and at high power end it provide min gain. If the input power is in between, the gain will be interpolated almost linearly. That is how Sam's expended log detector works, and we try to expend this concept from 10.7MHz IF2 signal to 1013.3MHz IF1 signal or even to the input of the MSA.
Lin

From: Sam
Topic: 9018 Message: 9035

It does sort of expand the range, by shifting it down so the range available at 5+ dBm, which is not very useable anyway, becomes useable.

The apparent range of the expanded log detector, or the regular log detector for that matter, gets extended when used in the MSA for two reasons. First, noise at the low end causes the response to flatten out, so a 1 dB change at the MSA input will cause less than that change at the VGA input. Second, the increasing insertion loss of Mixer 1 at the high end causes a similar effect for high end signals.

Also, if I recall correctly, your -3 dBm upper limit has to do with the VGA saturating. You can actually operate a ways into saturation as long as the VGA output keeps increasing with increasing input.
Sam W.

Topic: 9018 Message: 9036

As we only working at 1013.3MHz, it may not be a difficult work to construct a PIN attenuator. Or can find a product:
http://www.rflambda.com/pdf/voltageattenuator/RFVAT0102A30.pdf

DIY tutorial:
http://palgong.kyungpook.ac.kr/~ysyoon/Pdf/an1048.pdf

Lin
--- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@...> wrote:
>
> It can all work as long as you don't overload anything along the way. A VGA immediately before or after the cavity filter would have to be able to handle inputs of at least -15 or -20 dBm along with the desired signal without becoming saturated in order to work well in SA mode. And have low noise. As a practical matter, I suspect you would need a small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA noise.
>
> The expanded log detector was intended to be linear-in-db over as broad a range as possible, but because of our path calibration this linearity is not actually critical for the MSA. Any voltage-controlled mechanism would work that has high gain at low inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to require calibration at fine intervals. If would even be fine for the gain to hit its minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode attenuator could work, if it has reasonable temperature stability.

> >
> > Sam
> > My calculation is very conservitive. The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > >
> > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.

The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around

-99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > > >
> > > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.
> > > >

One way to make use of this would be to put a second VGA in front of the RBW filters. The IF2 amp might still be required, but with reduced gain--just enough to keep the noise level down. The second VGA could tie into the same control line as the first, and would have to have its gain limited to 20 dB or so to avoid the possibility of overload.

Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

9038. Zero Response and Spurs

Yahoo group: spectrumanalyzer (2011)

From: Sam
Topic: 9038 Message: 9038

Now that I have improved the lower limit for my MSA, I decided to repeat the graph of my zero response, which can now be seen hitting -128 dBm at 500 kHz. Photo is in the SamW photo album. This also demonstrates how you can get useful info in VNA mode well below the level of the "minimum visible signal" in SA mode. Had I thought of this earlier, I would have done this with the 30 dB amp when I had that in place. But that would also require recalibrating, which I don't feel like doing.

I also did a scan for the LO1 leakage spurs that arise from LO1 leaking through Mixer 1 and the cavity filter and reaching Mixer 2. That photo is also in the SamW album. I have a bunch of such spurs, but none is above -100 dBm. I suspect some of these actually arise from leakage of LO1 harmonics, which I plan to try to filter out.

Sam W.

9039. Re: Pre-Cavity Amp

Jurgen,
Also, I looked at my original test documentation for my expanded log detector and I got very solid response from -115 dBm to +5 dBm, when tested freestanding with a signal generator. Some time ago we did some experimentation with yours, but I think we need to compare yours with the original schematic.

Also, last I knew you had the experimental noise filter with an op amp in it, which turned out not to be such a great idea (my fault).

But I wouldn't worry about it until everything else is satisfactory, as even the numbers you quote will provide a good range inside the MSA due to the factors I mentioned.

Sam W.

>
> The apparent range of the expanded log detector, or the regular log detector for that matter, gets extended when used in the MSA for two reasons. First, noise at the low end causes the response to flatten out, so a 1 dB change at the MSA input will cause less than that change at the VGA input. Second, the increasing insertion loss of Mixer 1 at the high end causes a similar effect for high end signals.
>
> Also, if I recall correctly, your -3 dBm upper limit has to do with the VGA saturating. You can actually operate a ways into saturation as long as the VGA output keeps increasing with increasing input.

9040. Re: Zero Response and Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-19 22:32:26 UTC
From: inlinebeginner
Topic: 9038 Message: 9040

A buffer amplifier between LO1 and mixer4 would helpful. i.e. we need two buffer amplifers, one to isolate LO2 and one to isolate LO1.
A while ago, I putlished some photo here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/2017591641/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

by adding one more buffer amplifier between LO1 and mixer 4, it fixed the problem.
Lin

Lin,
Not bad for $1.71. That would work well if you used it preceding a 20-30 dB amp and could manipulate the control voltage (derived from the log detector output) so that it would be somewhere between 2.5 and 5 V when the MSA input signals are weak and a very steady value somewhere between 0.5 V and 1 V when the input reaches a level where no amplification is needed any more.

The attenuation curve has a bit of wiggle, but if the attenuation became fixed above a certain input level, any error caused by the wiggle would not mean much since it would only affect low level signals (-105 dBm vs. -105.3 dBm is no big deal), or you could simply calibrate at small intervals.

They don't show the effect of temperature on attenuation but they do show the effect on individual diode resistance. It seems reasonably small, especially if you are at normal room temperature or above, as the inside of the MSA would normally be.

Sam W.

A VGA immediately before or after the cavity filter would have to be able to handle inputs of at least -15 or -20 dBm along with the desired signal without becoming saturated in order to work well in SA mode. And have low noise. As a practical matter, I suspect you would need a small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA noise.
> > >
> > > The expanded log detector was intended to be linear-in-db over as broad a range as possible, but because of our path calibration this linearity is not actually critical for

the MSA. Any voltage-controlled mechanism would work that has high gain at low inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to require calibration at fine intervals. If would even be fine for the gain to hit its minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode attenuator could work, if it has reasonable temperature stability.

If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

> > > > >
> > > > > There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > > > >
> > > > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.

> > > > >
> > > > > One might even say that the pre-cavity amp is not all that necessary. I was just compulsive about getting a solid -120 to 0 dB range. Plus, I wanted to get an idea what type of range I would get with the SAW module, which I expect will come out in the ballpark of what I get with the pre-cavity amp.

One way to make use of this would be to put a second VGA in front of the RBW filters. The IF2 amp might still be required, but with reduced gain--just enough to keep the noise level down. The second VGA could tie into the same control line as the first, and would have to have its gain limited to 20 dB or so to avoid the possibility of overload.

allow signals to reach the VGA unless they will also reach the log detector. Otherwise, a strong signal can overload the VGA without the log detector knowing about it. That is the reason I use the arrangement RBW Filters->VGA->Noise Filter->log detector, with the Noise Filter always broader bandwidth than the RBW filter.
> > > > > > > >
> > > > > > > > > You actually could violate this rule for VNA use only, as long as there would never be a spurious signal strong enough to overload the VGA. That might be the case with a VGA located after the cavity filter (maybe even before the cavity) as long as the VGA never had gain greater than 30 dB or so. (The prime overload risk would come from leaked LO1.)

In this way, we can have larger dynamic range. The overall is a IF amplifer at 1013.3MHz but the BW is determined by the RBW filters.

Len,
Could you build a 5 cavity filter (instead of four).

Sam,
I have been following closely this discussion, to the point that I am considering a 5 cavity filter (instead of 4). Since the amplifier is to provide about 10 dB gain, I am looking at the MiniCircuts low noise coaxials like the ZRL-1150LN (NF=0.8), and specially the ZX60-1215LN (NF=0.4). What do you think?

Topic: 9038 Message: 9044

The LO2 isolation amp eliminated a broad range of leakage that seriously interfered with the usability of the MSA below 1 MHz, being more problematic the lower you went. If the spur at the RBW frequency bothers you, the additional amp for LO1 isolation might make sense, but if it only improves performance at one frequency, many people might not consider it worth the trouble.

I have found that for VNA use, if you use a narrow RBW, it is just random bad luck if you happen to run into one of the spurs, which aren't all that numerous. For SA use, if you try to densely cover a range that covers part of the 5-17 MHz range, you will likely run into a few spurs, and you can run into some outside that area, but if you know where the spurs are, they aren't all that bothersome, unless you happen to have some very strong ones.

Sam W.

This also demonstrates how you can get useful info in VNA mode well below the level of the "minimum visible signal" in SA mode. Had I thought of this earlier, I would have done this with the 30 dB amp when I had that in place. But that would also require recalibrating, which I don't feel like doing.
> >
> > I also did a scan for the LO1 leakage spurs that arise from LO1 leaking through Mixer 1 and the cavity filter and reaching Mixer 2. That photo is also in the SamW album. I have a bunch of such spurs, but none is above -100 dBm. I suspect some of these actually arise from leakage of LO1 harmonics, which I plan to try to filter out.

As far as the amp is concerned, it's a matter of taste, but I'm not sure it is worth great expense to lower the noise figure by a few dB. In fact, someone can correct me if I am wrong, but I think that if you have an amp with 7 dB gain (my actual value) followed by a cavity filter and Mixer 2 each with 6-7 db of loss, if the amp creates 3 dB of noise (re: input), that noise will itself be buried in resistor noise when it reaches the IF2 amp and be almost irrelevant.

As far as a 5-holer, that only makes sense if a tiny image frequency bothers you, or if creates an issue when a strong signal raises the overall "noise floor" due to limited "ultimate attenuation". By the way, if you already have a 4-holer, there is no reason you can't cascade it with a 1-holer. You don't have to start from scratch. In fact, you might consider doing 1-holer->amp->4-holer.

From: nealmartini
Topic: 9047 Message: 9047

Sam,

Have you ever tried to implement an averaging capability in the MSA software? I know the MSA output spectra have no phase syncronization, but averaging would definitely reduce the power spectrum's noise variance, which would help especially at the low levels your currently discussing.

Neal

I agree with Sam. 0.4dB may not have significant difference from 3.3dB for this applicaton. 1 holer + amp + 4 holer cavity might be the way we want to go. The SAW may have similar structure, SAW1 + amp + SAW2 + SAW3. As we could not get the SAW parts, the cavity filter experiment is the closest emulation. It may also benifit to those who do not want to change to SAW. If we use SAW, I hope we can get the part easily, it it too hard to find the SAW, cavity will still the traditional way to build the MSA.
For the SAW filter source, it really up to the quantity that we can order. If we can order 100K (this is a small number, if this filter is used in a mass product), I think the vendor would be really happy to provde them. If we only order 100, the vendor may not willing accept such a small order if there is no such part in stock, because the cost to reopen the production line may be much hgiher than what we paid to the vendor. On the other side, cavity filter is a home made filter, as long as you spend enough time and are patient enough, you should have one (maybe Len can sell one to you). It is controlled by yourself.
Lin

I am measuring 2.8 dB insertion loss at the diplexer 1G band, where there is just a 33pF cap. Does this match with what you have?

From: jghbeta
Topic: 9018 Message: 9050

My policy has always been not to go with a sng;le supplier item. I haven't seen a 1013 saw anywere else, it may be just a fluke. I will play with the saw but I am staying with the cavities.

Jim

From: william
Topic: 9051 Message: 9051

Hi All,
I just updated the web page:
http://scottyspectrumanalyzer.com/slim_sfa_1013.html
with more results. I played with the SAW/Amplifier section but have not yet installed the amplifier or the 3 dB input attenuator. I wanted to get a few more characterizations before I did that. You can consider this section of the web page as looking over my shoulder as I play.
Scotty

9052. Re: [spectrumanalyzer] Re: Pre-Cavity Amp

I already have a quote for an order of 325 SAWs. There was no hesitation on the supplier's part. I understand the issue of single sourcing, but my experience tells me that this is only a short term issue. The size and performance of the SAWs employed in the 1013 MHz filter are very compelling. That historically drives other similar applications that will drive similar SAW product developments and other manufacturers will jump in.

The order window for the group buy closes this Thursday. At that point I will be sending out the details to finalize the group buy. BTW, I have orders for 114 sets of parts for filters so far.

Neal

Re: Can I build five cavity filter?

I can do it, but ,maybe best to first ask our guru Scotty if he foresees any downs or even if there are any ups at all.

I would expect more attenuation another -2-3 db and perhaps steeper- complex phase shifts, ripples?

I was contemplating building a 1x and 2x filter for possible SAW projects.

So I could couple a current 4x and 1x proto and suck it and see.

I have qty 20 raw cut pipes and posts (spare) at the moment so no problem there.

Price of current 4x cavity = U$80 assembled and tested, so 5x cavity = U$100.

Postage for a 5x or 4x+1x may be a big price step the 4 x is 0.495 Kg just inside the OZ post office < 0.5Kg cheaper rate.

Regards

Len Spyker

Hi All
The LEE-39+ and ERA-33SM+ amplifier group buy demand has tailed off now, so I will shortly be getting a confirmed price for the quantity so far and will be in a position to produce an all in cost for your order.
Once that's done, I will give an order close date and then ask for payment by PayPal, using the personal/gift route of payment, I will use your PayPal postal address unless you state otherwise. My PayPal address to follow later.
If you have only just come across the Amp group buy and want to participate, please see messages 8958,8962 and 8986 for more information.
Regards
Steve g7was.

Hi Len,
 Since you bring that up....
A 5 banger is definitely an overkill. With 4 you can expect the image alias to be greater than -100 dBc. With 5 you can expect the image alias to be greater than -125 dBc. Over the many years I have used SA's, input image frequencies are rarely stronger than the signal of interest. Since the nominal dynamic range of the MSA is 100 dB, the image will not be seen.
 As Len suggests, there is a down side to using 5 cavities. The Coaxial Cavity filter is temperature sensitive to phase change. Only significant when in the VNA Mode. The extra cavity will increase this sensitivity 20 %. Perhaps, not a big deal, but still you will be adding more error when it is unnecessary.
Scotty

9057. Re: Incoherent Averaging

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-20 13:44:12 UTC
From: Sam
Topic: 9047 Message: 9057

Neal,
We accomplish a lot of averaging with the video filter. Mathematical averaging of multiple readings is used in the path calibration procedure, which requires about 5 seconds to produce a result.

Scanning with the XNarrow filter is already very slow and averaging multiple readings would make it even slower. I have thought about doing what I think is called "exponential averaging", where on each scan the old data is replaced with a weighted average of that data with the new data. This is actually the same as normal averaging except you are not averaging a fixed number of scans; you are always averaging all the data since the last Restart. The advantage of the exponential approach is that you don't have to save a lot of scan data in order to be able to drop the oldest when you add the newest. It would be very simple to implement in the software without creating additional data arrays.

It would still take a long time (i.e. many scans) to produce a full set of data with a lot of averaging, but at least you would be able to watch the full scans as they get refined. Depending on how well this works, it could make the XNarrow video filter unnecessary.

An issue that I have thought about without any conclusion is the difference between these two methods of averaging: (1) averaging voltages at the ADC, which the video filter does, and which is also the same as mathematically averaging ADC readings, and (2) averaging dBm readings, which are the values the ADC readings get converted into using the path cal file. The two are different, especially when the conversion from ADC to dBm is not linear. A related issue is that averaging power in dBm is different from averaging it in mW--I believe the arithmetic mean of dBm values is equal to the geometric mean of mW values. I think the bottom line is that averaging is a useful way to identify whether a signal is there, but does not necessarily produce a precise, unequivocal value for the signal strength.

Sam W.

9058. Re: Zero Response and Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-20 16:13:38 UTC
From: Sam
Topic: 9038 Message: 9058

Lin,
Your idea for an isolation amp on the LO1->Mixer 4 path made me curious about the source of the IF2 spur (assume IF2=10.7). Of course, it ultimately comes from the fact that when you are tuned to the IF frequency, LO1=LO2=LO3-10.7. Thus, if LO3 gets into Mixer 2, you will get the spur. Scotty's LO2 isolation amp prevents LO3 from leaking into LO2 via Mixer 3. As I understand it, that got rid of his IF2 spur (but not the unrelated DDS3 spur that is close by).

Your proposed amp prevents LO3 from leaking into Mixer 1, then through the cavity filter to Mixer 2. You reported that this zaps the remaining IF2 spur. What made me curious is that LO3 at this point is 21.4 MHz above the cavity center, and it should not be possible for a noticeable amount to pass through the cavity filter. In fact, I looked at the Mixer 1 output, and the level of LO3 was not even visible, (hence below -80 dBm), so even modest attenuation by the cavity filter would zap it. Yet I get the IF2 spur.

I believe I have figured out the mechanism, which we should be able to eliminate by filtering the Mixer 1 output to eliminate signals above 2 GHz.

LO3 leaks through Mixer 4 and the PLO1 module into Mixer 1. There it produces various mixing products, including 2LO1+LO3. (Remember, the second harmonic content of LO1 is extremely high.) Due to the periodic nature of cavity filters, a significant portion of this signal leaks through the cavity filter and mixes with LO2:

(2*LO1+LO3)-3*LO2=LO3-LO1=10.7 MHz (because LO1=LO2)

And there is your spur. I was originally thrown off track by the fact that the spur has the same width as the RBW, which suggested harmonics were not involved. But this mechanism does not involve a harmonic of LO3, even though it involves high frequency components.

The offending signal, 2*LO2+LO3, is above 3 GHz and should be easy to filter out. Similar filtering may help reduce the LO1 leakage spurs, so a filter that is strong above 2 GHz would be ideal.

If I am correct, the additional isolation amp would not be necessary.

Sam W.

From: Sam
Topic: 9038 Message: 9059

Well, I had a great theory but it was a load of bull. The answer to the IF2 spur is very simple. LO3 that leaks into LO1 produces IF1 directly in Mixer 1:

2*LO1-LO3=2*LO1 - (LO1+10.7) = LO1-10.7 = IF1

This is true when you tune to 10.7 MHz (=assumed IF2) because LO1=LO2=IF1+10.7, and LO3 always equals LO1+10.7. This IF1 of course zips right through the cavity filter to Mixer 2 where it mixes with LO2 to produce 10.7 MHz.

The bad news is that you can't eliminate this by filtering out high frequencies. I verified that in fact my Mixer 1 had IF1 output of about -100 dBm when tuned to 10.7 MHz.

The good news is that I tried a low pass filter to eliminate the leakage of LO1 harmonics, which zapped several of my LO1 leakage spurs, leaving just the ones near 8 MHz and 13.3 MHz (N=4) and the one near 21.4 MHz (N=1). I'm not sure why those survived.

Sam W.

9060. Amp group buy transformer addition if interested.

Yahoo group: spectrumanalyzer (2011)

Hi All
I have been thinking about having a play with some ADTT1-1 transformers, but the cost for three is very expensive. Would anybody be interested in increasing the numbers and bring the price down to a more acceptable level. It would just be an addition to the Amp order. Cost would be about £12 + p&p. If you are interested please reply using this email

Is that for 3 or 1, Steve?

Topic: 9038 Message: 9062

More good news on spurs. After adding a 1.1 GHz low pass filter to the cavity input, several of the "LO1 leakage spurs" were eliminated, but several remained. In addition, I still had the IF2 spur. After some poking around I realized that PLO1 and PLO2 in my build are adjacent to each other, and that if I pressed on the lid of PLO1 the remaining spurs dropped 2 dB. The lids on those modules overlap the fencing a tiny bit, so I ran a soldering iron around the edge while pressing down so the lid made better contact with the side fence. I got a 4 dB improvement for doing so on PLO1 and 4 more for doing it on PLO2, for a total reduction of 8 dB. That puts me in good shape for all the spurs from 5-22 MHz. Some were eliminated and the others were reduced so all are below -105 dBm, some well below that.

Here is what I believe I have established:

1. First, if your IF2 is 10.7 MHz, here are the spurs at issue; if you have a different IF2, the frequencies will change proportionately:

5.3500
7.1333
8.0250
8.5600
8.9167
9.1714
9.3625
12.0375
12.2286
12.4833
12.8400
13.3750
14.2667
16.0500
21.4000

The above are LO1 leakage spurs. Their distinguishing characteristic is that they all differ from 10.7 MHz by a multiple of 10.7/N, where N is any number 1 through 8.

In addition, there is the IF2 spur at 10.7 MHz.

2. I did not have visible spurs at all these frequencies, but the ones I did have were eliminated by the low pass filter, except the following:
8.025, 10.7, 13.375 and 21.4

All of the eliminated LO1 leakage spurs actually arise from leakage of LO1 harmonics, not LO1 fundamental.

While these remaining ones could be created by LO1 leakage through the cavity filter (except 10.7), they also have other mechanisms (see below)

3. The more stubborn spurs listed in 2 above were either caused by LO1 leaking directly to LO2 (or vice versa) or by poor isolation within the PLO modules. I inspected the lid joints before messing around, and they seemed solidly sealed, so I am not convinced there was direct leakage from one module to the other. So I tend to think the isolation between the two outputs in each module improved with the re-soldering. I'm out of my depth on this, but I wonder whether the isolation is improved when there is good brass-to-brass contact between lid and fencing so any lid current can reach ground without going through a lot of lead.

Before re-soldering the PLO lids, I removed my low pass filter, so it is conceivable that the remaining portion of the spurs listed in #2 will be eliminated when I restore it.

> > Your idea for an isolation amp on the LO1->Mixer 4 path made me curious about the source of the IF2 spur (assume IF2=10.7). Of course, it ultimately comes from the fact that when you are tuned to the IF frequency, LO1=LO2=LO3-10.7. Thus, if LO3 gets into Mixer 2, you will get the spur. Scotty's LO2 isolation amp prevents LO3 from leaking into LO2 via Mixer 3. As I understand it, that got rid of his IF2 spur (but not the unrelated DDS3 spur that is close by).
> >
> > Your proposed amp prevents LO3 from leaking into Mixer 1, then through the cavity filter to Mixer 2. You reported that this zaps the remaining IF2 spur. What made me curious is that LO3 at this point is 21.4 MHz above the cavity center, and it should not be possible for a noticeable amount to pass through the cavity filter. In fact, I looked at the Mixer 1 output, and the level of LO3 was not even visible, (hence below -80 dBm), so even modest attenuation by the cavity filter would zap it. Yet I get the IF2 spur.
> >

Topic: 9038 Message: 9063

I forgot to mention an important first step. For all <1 GHz signals I used conformable 0.086" coax. However, I found that the coax feeding the MO to PLO2 was leaking PLO2. I fixed that by adding solder to the cable. That improved a few spurs.

If I were to start from scratch, I would use nothing but hardline for any coax that carries or is connected to a module that handles >1GHz. I would also not direct-solder any coax (or maybe in some cases I would do so with one end with an SMA connector at the other end.) However, notwithstanding that, my MSA performance is very good.

Topic: 9047 Message: 9064

Sam,

A few comments on averaging:

1. You definitely need to use a scheme where you can see the spectrum evolve from scan to scan. I don’t know the subtleties of your software, but there are a lot of techniques around for efficiently doing running averages. Digital filters use this a lot.
2. The video filtering that is done by the capacitor at the input to the A to D is across frequency. If you make the assumption that the noise distribution across frequency bins is the same as the noise over time in a specific bin, you do average out some of the noise variations.
3. Averaging power bins over time is, in fact, a way of improving the accuracy of your signal power measurements. If the signal is assumed constant from sweep to sweep and the noise is random, averaging will reduce the erroneous readings that are caused by the noise being randomly added to the stable signal. The signal average will be constant. I don’t have any of my old textbooks with me where I am right now, but I believe the improvement available is something like 10 log sqrt (N), where N is the number of samples you average over. If my formula is right (might be 20 log???), you could get 5 dB of improvement by averaging 10 sweeps.
4.This type of averaging is commonly used in spectrum analyzers for these very reasons. It is also the scheme used in an oscilloscope that has an averaging option.

I think there is a lot to be gained by exploring it a bit.

Subject: [spectrumanalyzer] Re: Incoherent Averaging

Neal,
We accomplish a lot of averaging with the video filter. Mathematical averaging of multiple readings is used in the path calibration procedure, which requires about 5 seconds to produce a result.

Scanning with the XNarrow filter is already very slow and averaging multiple readings would make it even slower. I have thought about doing what I think is called "exponential averaging", where on each scan the old data is replaced with a weighted average of that data with the new data. This is actually the same as normal averaging except you are not averaging a fixed number of scans; you are always averaging all the data since the last Restart. The advantage of the exponential approach is that you don't have to save a lot of scan data in order to be able to drop the oldest when you add the newest. It would be very simple to implement in the software without creating additional data arrays.

It would still take a long time (i.e. many scans) to produce a full set of data with a lot of averaging, but at least you would be able to watch the full scans as they get refined.

Depending on how well this works, it could make the XNarrow video filter unnecessary.

An issue that I have thought about without any conclusion is the difference between these two methods of averaging: (1) averaging voltages at the ADC, which the video filter does, and which is also the same as mathematically averaging ADC readings, and (2) averaging dBm readings, which are the values the ADC readings get converted into using the path cal file. The two are different, especially when the conversion from ADC to dBm is not linear. A related issue is that averaging power in dBm is different from averaging it in mW--I believe the arithmetic mean of dBm values is equal to the geometric mean of mW values. I think the bottom line is that averaging is a useful way to identify whether a signal is there, but does not necessarily produce a precise, unequivocal value for the signal strength.

Sam W.

The real issue is whether additional averaging adds anything to the averaging accomplished by the video filters. In a purely digital system, software averaging is all you have. But the video filter, which averages the signal strength in dBm as opposed to all the voltage points in the time-domain signal, accomplishes a lot. With my video filter switch, which can use a filtering capacitor up to 100 uF, there isn't much noise left.

I was thinking about this incorrectly. I forgot about the wait time parameter in the MSA. Basically, your sitting on a frequency bin the width of your final filter and averaging out the noise with the A to D capacitor. Long wait + big Cap = Clean signal. I was initially thinking we had a scanning sweep that didn’t stop with my earlier comments. My bad!

The real issue is whether additional averaging adds anything to the averaging accomplished by the video filters. In a purely digital system, software averaging is all you have. But the video filter, which averages the signal strength in dBm as opposed to all the voltage points in the time-domain signal, accomplishes a lot. With my video filter switch, which can use a filtering capacitor up to 100 uF, there isn't much noise left.

> 3. Averaging power bins over time is, in fact, a way of improving the accuracy of your signal power measurements. If the signal is assumed constant from sweep to sweep and the noise is random, averaging will reduce the erroneous readings that are caused by the noise being randomly added to the stable signal. The signal average will be constant. I donâ□□t have any of my old textbooks with me where I am right now, but I believe the improvement available is something like 10 log sqrt (N), where N is the number of samples you average over. If my formula is right (might be 20 log???), you could get 5 dB of improvement by averaging 10 sweeps.

I have thought about doing what I think is called "exponential averaging", where on each scan the old data is replaced with a weighted average of that data with the new data. This is actually the same as normal averaging except you are not averaging a fixed number of scans; you are always averaging all the data since the last Restart. The advantage of the exponential approach is that you don't have to save a lot of scan data in order to be able to drop the oldest when you add the newest. It would be very simple to implement in the software without creating additional data arrays.
>
> It would still take a long time (i.e. many scans) to produce a full set of data with a lot of averaging, but at least you would be able to watch the full scans as they get refined. Depending on how well this works, it could make the XNarrow video filter unnecessary.
>
> An issue that I have thought about without any conclusion is the difference between these two methods of averaging: (1) averaging voltages at the ADC, which the video filter does, and which is also the same as mathematically averaging ADC readings, and (2) averaging dBm readings, which are the values the ADC readings get converted into using the path cal file. The two are different, especially when the conversion from ADC to dBm is not linear. A related issue is that averaging power in dBm is different from averaging it in mW--I believe the arithmetic mean of dBm values is equal to the geometric mean of mW values. I think the bottom line is that averaging is a useful way to identify whether a signal is there, but does not necessarily produce a precise, unequivocal value for the signal strength.

Neal,
Correct. In fact, if you use Auto Wait, the MSA takes repeated readings at each point until either the reading is stable or it decides that, due to noise, it will never fully stabilize. That way, you don't waste time waiting on flat areas of the graph.

Neal,
It's been around since at least 116-4e. It appears next to the normal Wait box. It is explained in the ReadMe file, which is in the zip file that contains the beta versions.

In any case, you should download the current beta, which I have just updated to 116-4q. There are several minor fixes and one important one. Previously, if you used the File menu to save the image or data, it was possible for the File Dialog to crash. That no longer happens.

I have noticed that many people save their images by using screen shots, which, depending on how you do it, saves the entire screen or the entire window (including menu bar and buttons). There is now no reason to do it that way. If you use File->Save Image or Edit->Copy Image, you will get just the graph image, plus the marker info below the graph and the other info on the right of the graph, without getting the menu bar or buttons.

Sam W.

9070. Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-21 21:16:55 UTC
From: Sam
Topic: 8735 Message: 9070

I have posted scans of my spurs in VNA mode, from zero to 22 MHz. They are in the SamW photo album:
<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/252922278/pic/list>

The low pass filter on the cavity input definitely helped with some spurs, but was not a cure-all. It was not quite as effective as I originally thought. There are still a few strong spurs, but all below -110 dBm. I believe some or all of those arise from construction defects that allow through-the-air leakage within the MSA enclosure. The graphs go down to -128 dBm, and show that there are numerous spurs when you get below -120 dBm, but those are not problematic.

In SA mode, there are fewer spurs. For example, the spur at IF2 goes away when I shift to SA mode.

There are also spurs on the slope of the zero response. I believe most or all of those are not at fixed frequency, but rather locate themselves relative to the tuned frequency and their level is "dBc" relative to the tuned signal strength. They may arise from DDS spurs and thus can also move around a bit.

I have a 7 dB amp at the cavity filter input. This not only provides the added low end range, but weakens all spurs by 7 dB except those that involve a signal passing from Mixer 1 to the cavity filter. That spur weakening does not occur until you re-calibrate with the amp in place.

Sam W.

9071. Amp/Transformer group buy closing soon.

I have sent out a finalised cost and payment request to all taking part. Most have paid. There are 8 still to pay. I would like to wrap this up.
So if you have a change of mind, please say. The closing date for orders is 23thDec; no more orders will be taken after that date. Payment deadline is the 27th Dec. I will then place the order but only for the people that have paid. So don't miss out.
Regards
And a happy Christmas to all.

Hi Sam,

As your VNA is a rapidly evolving beast, could you give us a snapshot of its evolutionary state, ie. IF2 amp gain, VGA filters, and levels throughout?

Thanks,

david

9073. Expanded Log Detector

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-22 13:37:27 UTC
From: Sam
Topic: 8735 Message: 9073

David
My Expanded Log Detector is as described on my web site, as is my IF2 Amp. I'm pretty sure I haven't changed it since I last updated the web site docs. The schematic changed since the original documentation was done, but the "Even More Updated Schematic and Layout" is current.

Here is a general indication of signal levels, prior to the implementation of the 7 dB pre-cavity amp. I think my Mixer 1 + cavity + Mixer 2 have about 22 dB of loss, so with -120 dBm at MSA input there would be about -142 dBm at the IF2 amp input. With 0 dBm at MSA input I get about -14 dB out of Mixer 1, which turns into -27 dBm at the IF2 amp. The IF2 amp has 28 dB gain so its output is -114 dBm to +1 dBm. That makes the max power to the RWB filters +1 dBm if my MSA input does not go above 0 dBm; if it does, there is the potential for 3 dB more to the filters. With the pre-cavity amp, all these numbers go up 7 dB. (The power at the low levels is actually a few dB higher than I stated, because the signal is mixed with substantial noise.)

My RBW filters are 600 Hz (amplifilter), 8 kHz (canned filter), 30 kHz (dual ceramic) and 400 kHz (dual ceramic). The signal then passes through the AD8330 VGA, then the noise filter, then the regular log detector. The combined VGA+filter+log detector act exactly like a log detector with extended range. In addition to the added range, the wiggle that exists in the response curve of the log detector gets "stretched" so the period of the wiggle is longer, which allows calibration to be done in larger steps.

I use the switched noise filter, which selects either 1 MHz or 15 kHz. I use the narrow noise filter only with the narrowest RBW.

It has been a while since I experimented with the noise filter, but I used to use a single 500 kHz noise filter (single ceramic) that worked quite well. As I recall, when my narrowest RBW was 2 kHz there was no benefit to switching to a narrow noise filter, but when I implemented the amplifilter it seemed like a good idea to build the switched noise filter.

My experiment with a 30 dB pre-cavity amp showed I could get substantially more range at the low end, so my noise filters are not a bottleneck, at least for the narrowest RBW. This may indicate that (unless I actually wanted to use the 30 dB amp) I would have been fine sticking with the fixed 500 kHz filter (plus a 6 dB pad, per the next paragraph). That would be handy because it requires just a single ceramic filter and can be built as an in-line device like an attenuator.

A key discovery that simplified the switched noise filter design is that there was actually an advantage to having some loss in the noise filter, as it caused the log detector to crank up the gain on the VGA a bit, putting the VGA into a lower noise region. Even 10 dB of loss was good.

I don't recall the signal levels at the VGA and log detector, but my ADC readings range from about 6800 to 25500.

As far as other customization of the MSA, I use my "Mixer 3 amp" module, which has dual ERA amps, one for Scotty's LO2 isolation amp and one as a buffer on the TG output, to provide output of -4 dBm while at the same time improving output return loss and preventing high frequency effects from LO1 or LO3 leaking through Mixer 3 and being reflected back in to varying degrees depending on the DUT. Having both amps in one module creates some isolation risk. When I tested it there seemed to be no problem but it is conceivable that with the extra range I have created recently I may have exposed some spurs that arise from leakage between those two amps.

My cavity filter is at 1045.3 MHz, a change I will have to undo if I switch to the SAW. (It's a simple Configuration change.) I have a dual amp module used as a splitter for LO3, in order to provide an LO3 output to use as the tracking generator for 2G mode, though this is probably unnecessary because you can just re-cable the LO3 line feeding Mixer 3, since you don't need the regular TG in 2G mode. (You can run that LO3 line to an external connector, with another connector leading back to Mixer 3, and either jumper the connectors together or remove the jumper to use LO3.)

That's about it.

From: Sam
Topic: 8735 Message: 9074

I realized I still have my original 500 kHz noise filter, so I tested it against the switched noise filter. The 500 kHz filter, with or without a 6 dB pad, loses approximately 3 dB at the low end. That's with my 7 dB pre-cavity amp. (I didn't test without the amp.) It's worth using if you have it, but maybe not worth building if you don't.

I think I got the effect of the pre-cavity amp backwards in my previous post. That amp results in a stronger signal to the VGA so you could get by with less noise filtering. This means if you don't use the pre-cavity amp, you need more noise filtering and the switched noise filter might provide more benefit at the low end. The difference might not be as much as you would think, because a stronger VGA input results in less VGA gain, so the increased signal level at the VGA output is much less than the increase at the input.

> Here is a general indication of signal levels, prior to the implementation of the 7 dB pre-cavity amp. I think my Mixer 1 + cavity + Mixer 2 have about 22 dB of loss, so with -120 dBm at MSA input there would be about -142 dBm at the IF2 amp input. With 0 dBm at MSA input I get about -14 dB out of Mixer 1, which turns into -27 dBm at the IF2 amp. The IF2 amp has 28 dB gain so its output is -114 dBm to +1 dBm. That makes the max power to the RWB filters +1 dBm if my MSA input does not go above 0 dBm; if it does, there is the potential for 3 dB more to the filters. With the pre-cavity amp, all these numbers go up 7 dB. (The power at the low levels is actually a few dB higher than I stated, because the signal is mixed with substantial noise.)

9076. Reducing Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-22 18:22:43 UTC
From: Sam
Topic: 9076 Message: 9076

Since I just spent some time locating and trying to reduce my spurs, I thought I would post a list of hints:

1. You should carefully inspect every soldered seam in your lids and fencing. Likewise, inspect where coax is soldered to a connector or directly to the board.

2. Be sure all connectors are tight. It is amazing how much leakage you can get from an SMA connector being just slightly loose. That is true even at 10.7 MHz. Ideally, they should be just slightly tighter than hand tight.

3. Sometimes a connector binds a bit when it is not close to being tight. If this happens within the first turn or two, it is probably cross-threaded. It may also happen after several turns, so you think it is "hand tight", but if you turn it a little more with a tool it breaks free and may go another turn or two. I use the torque tool that Lin recommended; I think they jacked the price up a bit but it is still just $25: <http://www.kcrproducts.com/catalog/product_info.php?products_id=38&osCsid=7nt46iogac496equ6ptba799p4>

This not only gets the proper torque (even for right angle connectors that you have to access from the top), but is handy for reaching through a maze of cables where it is hard to get your fingers.

4. To actually locate a bad spot, I have found sniffers to be not very useful, unless you have a massive leak. Somehow they seem to pick up low level signals even if you touch them to the outside of the chassis. It is hard to localize the source of the problem with a sniffer, partly because you cannot limit the sniffer to picking up signals from just one module or cable. Also, the spur problem may be caused by very high frequencies beyond the range of your sniffer.

5. I have found poking my finger around to be the best technique. By putting my finger between two adjacent cables, or around the seams of a lid, or simply pressing on things, I can tell if something is going on there. Whether your finger makes the spurs better or worse, you have found something. To make this feasible, you may have to focus on a particular spur so you can have rapid scans to make it faster to see whether your finger is making a difference.

6. You may find that moving the power and logic wires affects spurs. I don't think that is necessarily an indication that RF is leaking out of modules through those wires. I think it is more likely that the wires affect through-the-air crosstalk that starts and ends elsewhere.

7. Crosstalk between the two outputs of each PLO, or between mixer inputs and outputs is a definite candidate for causing spurs, though it's hard to do anything about that other than maybe put a small capacitor somewhere or use microwave absorbing material. (Also, be sure the SMA connector pins don't stick up in the air.) I know some people use carbon-bearing anti-static foam for this purpose, but I did some tests to see what effect various materials have on leakage between an input and output connector in an otherwise empty metal

box, and the foam did nothing. The best practical material I found was bare FR-4, which kicks in slowly above 1 GHz and is pretty effective at 3 GHz. I didn't try the expensive true microwave stuff.

8. Conformable cable (the tin-dipped flexible shield type) can be a problem, especially where two cables are close together and/or they are bent sharply. The specs for such cable are normally quite good, but maybe you have cheap cable or maybe bending created openings in the shield. You can fix this problem by adding solder to the shield where necessary.

" With 0 dBm at MSA input I get about -14 dB out of Mixer 1"
Looks like at high power Mixer1 insertion loss is far away from 7dB normal value. I think we need to characterize mixer 1 at hihg power, to see what the insertion loss is.

As you add 7dB gain in PreCavity Amp, the RBW may see 7dBm at 0dBm MSA input. To avoid this overdriving, you may consider to change the 28dB IF2 back to Scotty's IFA2 (19.5dB gain), and adjust the VGA range. Before you adjust your VGA, the VGA gain seems to be 42dB at low power (-125dBm at MSA input). This VGA can work up to 54dB gain, therefore, you may be able to shift it. i.e. you move about 7dB gain from RBW input side to its output side to avoid RBW overdriving, while the total gain still keeps the same.

Lin

If you can use the full range of VGA, you may use Scotty's original

9079. Re: Expanded Log Detector

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-23 14:49:21 UTC
From: Sam
Topic: 8735 Message: 9079

Lin,
If you think of the mixer as using an LO to turn the RF on and off, what happens at high RF power is that the RF itself is able to partly turn the diodes on and off, so you get less "mixing" action. If I go from 0 dBm to 10 dBm at the MSA input, Mixer 1's output at IF1 increases only 3 dB.

Scotty's IF2 amp is a dual unit with a total of 40 dB gain. Even with the 7 dB pre-cavity amp, my total pre-RBW gain is only 35 dB. The RBW filters might still receive more power than you would normally use for a filter, creating considerable distortion, but it is a safe level. (Even the 40 dB gain appears to be safe.)

Due to distortion in Mixer 1, you would normally keep the input level well below 0 dBm when in SA mode, unless you simply want to measure the approximate power level. And in VNA modes the input level will normally be no higher than the TG level. So my goal for MSA inputs of 0 dBm and a little bit higher is just to get modest responsiveness and not destroy anything.

Lowering the IF2 amp gain and raising the VGA gain increases the noise level by partially bypassing the noise filtering done by the RBW filters.

Sam W.

9080. SAW 1013 MHz Filter Group Buy Notification

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-23 18:51:32 UTC
From: nealmartini
Topic: 9080 Message: 9080

SAW Filter Orderers,

If you ordered set(s) of SAW filter components through the group buy process we are doing, you should have received a direct email from me notifying you about how to complete the order process and make payment through PayPal.

If you did not receive that email do one of the following:
1. Check the files in your SPAM blocker to make sure the email didn't get Spam filtered out.
2. If the SPAM check doesn't show anything, send me a direct email (nealmartini@...) and I will resend you the instructions.

Neal

9081. Amp/Transformer Group buy CLOSED for orders.

Yahoo group: spectrumanalyzer (2011)

This is a good VGA: 250MHz to 4GHz, Dual 22dB each.
http://www.maxim-ic.com/datasheet/index.mvp/id/6573
Less than $6 if you buy from digikey.
http://search.digikey.com/scripts/DkSearch/dksus.dll?lang=en&site=us&KeyWords=max19790

250MHz to 4000MHz RF Frequency Range
Integrates Two Analog Attenuators in One Monolithic Device
Flexible Attenuation-Control Ranges
22dB (per Attenuator)
44dB (Both Attenuators Cascaded)
2.4dB 1500MHz Insertion Loss (per Attenuator)
Linear dB/V Analog Control Response Curve Simplifies Automatic Leveling Control and Gain-Trim Algorithms
Excellent Attenuation Flatness Over Wide Frequency Ranges and Attenuation Settings
Low 7.3mA Supply Current
Single +5.0V Supply Voltage

The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > > > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

Otherwise, a strong signal can overload the VGA without the log detector knowing about it. That is the reason I use the arrangement RBW Filters->VGA->Noise Filter->log detector, with the Noise Filter always broader bandwidth than the RBW filter.
> > > > > > > > >
> > > > > > > > > > You actually could violate this rule for VNA use only, as long as there would never be a spurious signal strong enough to overload the VGA. That might be the case with a VGA located after the cavity filter (maybe even before the cavity) as long as the VGA never had gain greater than 30 dB or so. (The prime overload risk would come from leaked LO1.)

Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

9083. MSA_version116_4q_Beta.zip Can't Load Third Filter Data

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-26 04:15:42 UTC
From: nealmartini
Topic: 9083 Message: 9083

Sam

I downloaded your MSA_version116_4q_Beta.zip and I am having a problem when I try and add my third filter to the RBW filter list. I copied my calibration files from an older version of the softare so I wouldn't have to recalibrate. I can add the first two RBW filter datae in the configuratons manager, but if I add a third RBW filter I get a divide by zero error when I try ad start the program.

I must be doing something stupid, but I have trie everything I could think of without success. Help!

Thanks
Neal

Neal,
There must be something odd in the path calibration file for the offending path, such as two entries for the same ADC value. Could you email me the file?

By the way, you could just replace the old program files (.bas, .tkn and .exe) and you wouldn't have to do anything to the configuration or calibration files. If you are switching from version 115, or a very old version of 116, you can still replace program files but have to perform a couple of additional steps (per the introduction of the ReadMe file).

Sam W.

9085. SAW Page Update

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-26 18:01:19 UTC
From: william
Topic: 9085 Message: 9085

Hi All,
I have been happily playing with the SAW Filters. I have updated the web page:
http://scottyspectrumanalyzer.com/slim_sfa_1013.html
to include more good poop. For example, Len asked for S21 data for the Cavity Filter. I assume for comparison for his latest build.
The next thing to do is actually install the SAW Filters into the Original MSA and take some data. I will update the page to include that.
Scotty

9086. Re: Pre-Cavity Amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-27 15:21:41 UTC
From: inlinebeginner
Topic: 9018 Message: 9086

Sam
The high power performance can be improved with the PIN attenautor.
I createded a PIN attenuator and attached it at a 20dB amplifer to be the pre-cavity amp.
The PIN attenuator range is about -12dB to -32dB,test result is here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/1951922862/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc
It shows that the dynamic range is -120 to +5dBm with 7.5kHZ RBW fitler. With 1kHz RBW filter, it would be -128 to +5dBm.
The curve was measured on a MSA model with your expended log detector. The measurement step is 1dB between -125 to -100dBm, -10 to +5dBm; and 5dB step betwee -100 to -10dBm.
Form the curve, we can see, if we do not put this PIN atten, -8dBm to 0dBm can not be used on my model, the curve goes down if we zoom in.
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/855170073/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc

The PIN attenuator SLIM model photo is here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/915382685/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc

can't allow signals to reach the VGA unless they will also reach the log detector.
Otherwise, a strong signal can overload the VGA without the log detector knowing about it.
That is the reason I use the arrangement RBW Filters->VGA->Noise Filter->log detector, with
the Noise Filter always broader bandwidth than the RBW filter.
> > > > > > > >

> > > > > > > > > > You actually could violate this rule for VNA use only, as long as there would never be a spurious signal strong enough to overload the VGA. That might be the case with a VGA located after the cavity filter (maybe even before the cavity) as long as the VGA never had gain greater than 30 dB or so. (The prime overload risk would come from leaked LO1.)

Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

9087. Re: Pre-Cavity Amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-27 16:56:46 UTC
From: Sam
Topic: 9018 Message: 9087

Lin,
That does solve the saturation problem nicely. Mine does not encounter that saturation, and maybe it has to do with a change I made as an experiment, which I didn't think had much effect but maybe it did affect the saturation point.

Referring to the current schematic, my Rx was replaced by a 0.1 uF capacitor, and my R2 is 6.8k rather than 10k.

Also, what noise filter are you using?

It might be helpful to identify where the saturation is occurring. With the input level near the point of saturation, check the RF levels at the IF2 amp input and output, and the VGA input and output.

It may partly be a matter of my MSA having higher losses in the initial stages.

Sam W.

A VGA immediately before or after the cavity filter would have to be able to handle inputs of at least -15 or -20 dBm along with the desired signal without becoming saturated in order to work well in SA mode. And have low noise. As a practical matter, I suspect you would need a small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA noise.
> > > > > >
> > > > > > The expanded log detector was intended to be linear-in-db over as broad a range as possible, but because of our path calibration this linearity is not actually critical for the MSA. Any voltage-controlled mechanism would work that has high gain at low inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to require calibration at fine intervals. If would even be fine for the gain to hit its minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode attenuator could work, if it has reasonable temperature stability.

> > > > > > >
> > > > > > > Sam
> > > > > > > My calculation is very conservitive. The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > > > > > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

> > > > > > > >
> > > > > > > > There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > > > > > > >
> > > > > > > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.
> > > > > > > >
> > > > > > > > One might even say that the pre-cavity amp is not all that necessary. I was just compulsive about getting a solid -120 to 0 dB range. Plus, I wanted to get an idea what type of range I would get with the SAW module, which I expect will come out in the ballpark of what I get with the pre-cavity amp.

One way to make use of this would be to put a second VGA in front of the RBW filters. The IF2 amp might still be required, but with reduced gain--just enough to keep the noise level down. The second VGA could tie into the same control line as the first, and would have to have its gain limited to 20 dB or so to avoid the possibility of overload.

Lin, do you have a schematic for this PIN attenuator?

Jurgen

Jurgen
I will publish it as soon as I finalize it and will tell you at that time. If you want to try a preliminary version (most likely is the final version, I did not see any layout errors, currently, I am working on part list), I can eamil you.
Lin

Sam
The IF2 Amp on my test model is not made of OP amp, it is emulated with one 13dB amplifier+ 6dB pad + 20dB amplifer (ERA-5). That might be the reason that I saw it was saturated at -8dBm.
Later I will check what you suggested.
Lin

could manipulate the control voltage (derived from the log detector output) so that it
would be somewhere between 2.5 and 5 V when the MSA input signals are weak and a very
steady value somewhere between 0.5 V and 1 V when the input reaches a level where no
amplification is needed any more.
> > > >
> > > > The attenuation curve has a bit of wiggle, but if the attenuation became fixed
above a certain input level, any error caused by the wiggle would not mean much since it
would only affect low level signals (-105 dBm vs. -105.3 dBm is no big deal), or you could
simply calibrate at small intervals.

immediately before or after the cavity filter would have to be able to handle inputs of at
least -15 or -20 dBm along with the desired signal without becoming saturated in order to
work well in SA mode. And have low noise. As a practical matter, I suspect you would need a
small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA
noise.
> > > > > > >
> > > > > > > The expanded log detector was intended to be linear-in-db over as broad a
range as possible, but because of our path calibration this linearity is not actually
critical for the MSA. Any voltage-controlled mechanism would work that has high gain at low
inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to
require calibration at fine intervals. If would even be fine for the gain to hit its
minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode
attenuator could work, if it has reasonable temperature stability.

> > > > > > > > My calculation is very conservitive. The -120dBm input is map to the linear
area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e.
the 120dBm is very decent measurement. If we just want to identify the signal above the
noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use
1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original
Scotty's log detector, not the expended log detector. Your expended log detector actually
contains one VGA already.
> > > > > > > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise
floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level
is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm,
log detector has very good linearity, therefore, if we map -91dBm back to MSA input with
the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input
-128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB
gain, the signal will show up at log detector as -99dBm, which is within log detector

response range.

> > > > > > > > > If you rarely need the low levels, you can leave the internal amp at 7 dB, or even leave it out, but add an external amp when necessary.
> > > > > > > > >
> > > > > > > > > There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > > > > > > > >
> > > > > > > > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.
> > > > > > > > >
> > > > > > > > > One might even say that the pre-cavity amp is not all that necessary. I was just compulsive about getting a solid -120 to 0 dB range. Plus, I wanted to get an idea what type of range I would get with the SAW module, which I expect will come out in the ballpark of what I get with the pre-cavity amp.

Sam
The RBW filter I was using is 7.5kHz. My 1kHz RBW filter is centered at 10.111MHz, it will not work with a 10.7MHz 200kHz BW noise filter. I plan to build a 10.695MHz 1kHz BW filter recently.
With 1kHz filter, we would have -128dBm to +5dBm dynamic range.
By the way, the cavity filter I was using is the recent built, it has only 4.2dB insertion loss, that might be another factor that I saw saturation but you did not see.
Lin

A VGA immediately before or after the cavity filter would have to be able to handle inputs of at least -15 or -20 dBm along with the desired signal without becoming saturated in order to work well in SA mode. And have low noise. As a practical matter, I suspect you would need a small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA noise.
> > > > > > >
> > > > > > > The expanded log detector was intended to be linear-in-db over as broad a range as possible, but because of our path calibration this linearity is not actually critical for the MSA. Any voltage-controlled mechanism would work that has high gain at low inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to require calibration at fine intervals. If would even be fine for the gain to hit its minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode attenuator could work, if it has reasonable temperature stability.

i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > > > > > > > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

> > > > > > > > > > There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > > > > > > > > >
> > > > > > > > > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.
> > > > > > > > > >
> > > > > > > > > > One might even say that the pre-cavity amp is not all that necessary. I was just compulsive about getting a solid -120 to 0 dB range. Plus, I wanted to get an idea what type of range I would get with the SAW module, which I expect will come out in the ballpark of what I get with the pre-cavity amp.

> > > > > > > > > > > Actually, you can let signals get to the VGA but not the log detector as long as the max gain of the VGA won't allow it to be overloaded by such stray signals. One way to make use of this would be to put a second VGA in front of the RBW filters. The IF2 amp might still be required, but with reduced gain--just enough to keep the noise level down. The second VGA could tie into the same control line as the first, and would have to have its gain limited to 20 dB or so to avoid the possibility of overload.
> > > > > > > > > > >

> > > > > > > > > > > A fundamental limitation of the VGA+log detector concept is that you can't allow signals to reach the VGA unless they will also reach the log detector. Otherwise, a strong signal can overload the VGA without the log detector knowing about it. That is the reason I use the arrangement RBW Filters->VGA->Noise Filter->log detector, with the Noise Filter always broader bandwidth than the RBW filter.
> > > > > > > > > > >
> > > > > > > > > > > You actually could violate this rule for VNA use only, as long as there would never be a spurious signal strong enough to overload the VGA. That might be the case with a VGA located after the cavity filter (maybe even before the cavity) as long as the VGA never had gain greater than 30 dB or so. (The prime overload risk would come from leaked LO1.)

In this way, we can have larger dynamic range. The overall is a IF amplifer at 1013.3MHz but the BW is determined by the RBW filters.

> > > > > > > > > > > > > > > My minimum visible signal with 600 kHz RBW is -122 dBm. My goal was to get a stable signal at -120 dBm. Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

9092. 9 coax filters built and shipped

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-28 09:05:07 UTC
From: spyker49
Topic: 9092 Message: 9092

Over the last week with some Santa's little helpers (a few beers) and the Australian Post Kangeroos, I shipped:

4 coax filters to France, 3 of these were kits.
Merci beaucoup mes amis de électronique. (Blame Yahoo translator).
2 coax filters to the USA. One at 1.0453 GHz.
1 coax filter to the UK.
2 coax filters to hot summer time OZ, Victoria and Queensland.
I hope that helps get your SAs fully operational.

That wraps up the coax filter batch production for another year.
Over the years 40 filters have been made. I always welcome feedback good or bad.

Built a 2x cavity filter for fun but have no reference unit plots. Any one with a 2x cavity plot or link please send it to me.

Regards Len Spyker

9093. NDK 10P7D filter response

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-28 09:48:12 UTC
From: davidhooau
Topic: 9093 Message: 9093

Oh Wise Ones,

I've built an RBW filter using the NDK 10P7D which is readily available on EBay. A happy snap is here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/319694121/pic/444836578/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

Can anyone advise what the two "shoulders" 20kHz either side of the response might be?

Thanks,

davidh

9094. RE: [spectrumanalyzer] Re: Cavity filter construction (Len's soldering hints and secrets) 5 CAVITIES

Topic: 9053 Message: 9094

Hi Len,

Is it possible to have a 5x cavity ?
Is it too late perhaps ?
Answer via my email.

Thanks a lot.

Best regards,
Ennio

Importance : Haute

Re: Can I build five cavity filter?

I can do it, but ,maybe best to first ask our guru Scotty if he foresees any downs or even if there are any ups at all.

I would expect more attenuation another -2-3 db and perhaps steeper-complex phase shifts, ripples?

I was contemplating building a 1x and 2x filter for possible SAW projects.

So I could couple a current 4x and 1x proto and suck it and see.

I have qty 20 raw cut pipes and posts (spare) at the moment so no problem there.

Price of current 4x cavity = U$80 assembled and tested, so 5x cavity = U$100.

Postage for a 5x or 4x+1x may be a big price step the 4 x is 0.495 Kg just inside the OZ post office < 0.5Kg cheaper rate.

Regards

Len Spyker

9095. NDK 10P7D filter response

David,
My guess is that they result from modulation in your LO1 resulting from ripple on the +20V line, and have nothing to do with the filter itself. Try putting another 10 uF cap on top of the one in PLO1 and do the same for the ones on the control board in the voltage doubler. Be sure to use X5R or X7R capacitors. You might have to do the same in PLO3 as well.
Sam W.

9098. Re: Pre-Cavity Amp

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-28 15:02:23 UTC
From: Sam
Topic: 9018 Message: 9098

Lin,
You might try adding a 6 dB attenuator at the IF2 amp output with and without the 7 dB pre-cavity amp. That might solve the saturation problem. It would likely worsen the low end noise, but yours seems extremely good for a 7.5 kHz RBW.
Sam W.

A VGA immediately before or after the cavity filter would have to be able to handle inputs of at least -15 or -20 dBm along with the desired signal without becoming saturated in order to work well in SA mode. And have low noise. As a practical matter, I suspect you would need a small fixed gain low-noise amp followed by a VGA in order to minimize the effects of VGA noise.
> > > > > > >
> > > > > > > The expanded log detector was intended to be linear-in-db over as broad a range as possible, but because of our path calibration this linearity is not actually critical for the MSA. Any voltage-controlled mechanism would work that has high gain at low inputs and drops the gain at higher inputs, as long as the drop is not so abrupt as to require calibration at fine intervals. If would even be fine for the gain to hit its

minimum at fairly low input levels, such as -90 dBm. Something as simple as a PIN diode attenuator could work, if it has reasonable temperature stability.

> > > > > > > > > > My calculation is very conservitive. The -120dBm input is map to the linear area -90dBm of log detector, and the noise floor of log detector is around -100dBm. i.e. the 120dBm is very decent measurement. If we just want to identify the signal above the noise floor, the calculated signal leve at MSA input should be around -128 dBm. Also, I use 1kHz RBW filter in my calculation, not 600Hz, the log detector is also the original Scotty's log detector, not the expended log detector. Your expended log detector actually contains one VGA already.
> > > > > > > > > > Here is how I calculated: The overall NF=16dB, overall gain 29. The noise floor at log detector input: -174 +16 + 29 + 30 = -99dBm. Log detector minimum input level is around -99dBm, at that area is very non-linear. However, starting from -91dBm to +15dBm, log detector has very good linearity, therefore, if we map -91dBm back to MSA input with the 29dB gain, the signal level will be -91-29=-120dBm. That does not say if we input -128dBm the log detecto won't reponse. becasue if we input -128 at MSA input, with the 29dB gain, the signal will show up at log detector as -99dBm, which is within log detector response range.

> > > > > > > > > > There is a little-known feature of the software called Front End Compensation, where you can specify a front end that you have added (such as an amp or attenuator) and it will use a calibration file to adjust the readings. You can use the MSA to create the calibration file. This is only needed for SA mode, since in VNA modes the regular operating calibration takes care of the front end.
> > > > > > > > > >
> > > > > > > > > > Adding attenuators or amps to the input is a way of shifting but not increasing the "simultaneous dynamic range". But it seems to me that if you get that range to 120 dB, the ability to shift it up or down with an attenuator or amp is all you are likely to need. If you have a 20 dB amp for getting to low signals, and a 20 dB attenuator (or maybe a couple), you'll be able to reach everything you want to reach.
> > > > > > > > > >

> > > > > > > > > > > One might even say that the pre-cavity amp is not all that necessary. I was just compulsive about getting a solid -120 to 0 dB range. Plus, I wanted to get an idea what type of range I would get with the SAW module, which I expect will come out in the ballpark of what I get with the pre-cavity amp.

One way to make use of this would be to put a second VGA in front of the RBW filters. The IF2 amp might still be required, but with reduced gain--just enough to keep the noise level down. The second VGA could tie into the same control line as the first, and would have to have its gain limited to 20 dB or so to avoid the possibility of overload.
> > > > > > > > > > >

Otherwise, a strong signal can overload the VGA without the log detector knowing about it. That is the reason I use the arrangement RBW Filters->VGA->Noise Filter->log detector, with the Noise Filter always broader bandwidth than the RBW filter.
> > > > > > > > > > > > > >
> > > > > > > > > > > > > > > You actually could violate this rule for VNA use only, as long as there would never be a spurious signal strong enough to overload the VGA. That might be the case with a VGA located after the cavity filter (maybe even before the cavity) as long as the VGA never had gain greater than 30 dB or so. (The prime overload risk would come from leaked LO1.)

In this way, we can have larger dynamic range. The overall is a IF amplifer at 1013.3MHz but the BW is determined by the RBW filters.

> > > > > > > > > > > > > > > My minimum visible signal with 600 kHz RBW is -122 dBm. My goal was to get a stable signal at -120 dBm. Such signal is now very visible, and if I place a marker on it, the value varies (noise) from scan to scan by about 2 dB. As far as I am concerned, that is excellent accuracy for such a low level signal. I can actually get a

measurable response below -128 dBm, but if the ADC change per dB is too small, a small bit of noise creates a very erratic graph. So I calibrated down to -128 dBm, but I don't expect much accuracy under -120 dBm.

9099. Expanded Log Detector Input Transformer

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-28 15:16:01 UTC
From: Sam
Topic: 9099 Message: 9099

The input transformer of the VGA in the Expanded Log Detector is specified as a Coilcraft type, with a Minicircuits alternate. The alternate is incorrect and should be TC16-161TG2. The one previously specified is TC16-1T, which has a lower spec of 20 MHz. If you used the TC16-1T, it should work fine but the insertion loss is a little higher, so conceivably the noise performance is a little worse.

I personally prefer Coilcraft but the Minicircuits transformers are fine.

Sam W.

Hello Davidh,

I just bought one of these filters as well.
Could you please let me know what matching network you used.

Thanks, Jurgen

David,
Another question, in your Photo Album you show a picture called
exp_log_det_shielded.
It shows that your linear range expands pretty well up to +10dBm.
How did get there?
I seem to have difficulties getting it to 0dBm. I am using a 500kHz
noise filter.

Sam,

Bingo!

I replaced the old voltage doubler with your LM2733X design, and the ripple is gone. Damned if I know why I haven't picked this up before. New photo:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/319694121/pic/1716957183/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

Thanks!

davidh

Try putting another 10 uF cap on top of the one in PLO1 and do the same for the ones on the control board in the voltage doubler. Be sure to use X5R or X7R capacitors. You might have to do the same in PLO3 as well.

Hi Jurgen,

I calculated 3.2uH and 70pF, but ended up using 3.8uH and 65pF, probably as my inductors were pretty low Q (~25).

I need to source some cores and learn about winding my own inductor. Any web references would be appreciated.

Cheerio,

davidh

Try "mini ring core calculator" by DL5SWB,
http://www.dl5swb.de/html/software_for_amateur_radio.htm , his dB
calculator is preety cool as well.

Geoff

Subject: [spectrumanalyzer] Re: NDK 10P7D filter response

Hi Jurgen,

I calculated 3.2uH and 70pF, but ended up using 3.8uH and 65pF, probably as
my inductors were pretty low Q (~25).

I need to source some cores and learn about winding my own inductor. Any web
references would be appreciated.

Cheerio,

davidh

9105. SA/VNA control bit

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-29 09:11:21 UTC
From: davidhooau
Topic: 9105 Message: 9105

Folks,

I'm building the input switch from the recent group buy. Has a logic bit been assigned to the SA/VNA switching function (SV in the schematics)? It appears that U4-bit6 is available, but is marked as "spare".

Thanks,

davidh

Jurgen,

Checkout the "Toroid King" as a core supplier and for toroid reference info.

Hi Jurgen,

I didn't get much over 0dBm with the VGA, maybe to +2dBm, but I'm running a really low IF2 amp gain (about 20dB) with a 3dB pad in the input mixer abd about 8dB loss in both mixer 1 and 2. I was waiting to finish some additional work before getting back to it, including extra RBW filters, the IF2 opamp stage and a pre-cavity gain stage.

I'll try to get some additional results in the next couple of weeks.

Thanks David,

I am in the process of lowering IF2 gain. Started out with Scotty's 38dB
amp, added one 6dB pad and did some more testing.
May add one more 6dB pad, not sure yet. Need to plot the linear range again.

Jurgen

9109. Re: SA/VNA control bit

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-29 13:32:46 UTC
From: Sam
Topic: 9105 Message: 9109

David,
There is no bit assigned to control SV (switching between SA and VNA inputs). My thought is that at this point it is best done with a manual switch, for a couple of reasons. First, it is not that common to need to switch rapidly between SA and VNA, so it is not a burden to do it manually. Second, when in SA mode you don't want anything attached to Transmission and Reflection inputs, and when in VNA mode you don't want anything attached to SA input. So when you switch modes you need to mess with cabling anyway (unless you are not dealing with low level or high frequency signals so isolation is not a big deal). If you have to switch cables, flipping a switch is not a significant additional step.

Finally, there may be reasons to do unusual things, such as using Transmission for a second SA input, or using the SA input for both SA and VNA, the way we do now. With a manual switch, the software does not interfere with how you use the inputs.

There is actually no reason to use the Transmission/Reflection inputs unless you need to measure both. If you are measuring only one, it is perfectly feasible to use the SA input.

The software does operate the bit for switching between Transmission and Reflection, but for example if you use the SA input of the input switch for both SA and VNA, it's up to you to attach the appropriate cable to the SA input and the software switching of the Transmission/Reflection inputs is then irrelevant.

(Note also that at the moment the software does not gather Transmission and Reflection data in one step. You need to scan in Transmission mode, then switch to Reflection mode, or vice-versa. Even once this is combined into one button, it will require separate scans to gather each type of data.)

Sam W.

9110. Re: NDK 10P7D filter response???? VGA

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-29 14:13:16 UTC
From: Sam
Topic: 9093 Message: 9110

We again have a messed up topic heading caused by starting a new thread by replying to an irrelevant one.

On the actual topic of the VGA: I think what you need to do is adjust the IF2 gain until the high end saturates about where you want it to. (It probably won't be the IF2 amp that saturates; it will likely be the VGA output.) I went for 0 dBm, because it is a nice round number. There are several factors to consider. First, in VNA mode you normally won't have inputs higher than your TG level, so any range above that point is irrelevant. That would argue for going with -5 dBm or -10 dBm. On the other hand, if you go for 0 dBm, your Mixer 1 will be experiencing increasing insertion loss, so by adding 1 dB to the VGA's high end ability you may get 2 dBm of additional high end at the MSA input, because it may take that extra 2 dB at the MSA input to increase the VGA input by 1 dB. So in a sense you get a few dB of free extra range by using the MSA input at levels that start to overload Mixer 1.

Of course, above -5 dBm or so at the MSA input, distortion in SA mode will be strong, phase measurements will be less precise, and performance over frequency will likely be somewhat different than that captured in Frequency Calibration.

Bottom line, determining the max useable high end input level is a matter of personal preference.

If you have the high end adjusted where you want it, and then decide to add the pre-cavity amp, you'll probably need to reduce the IF2 amp gain by the amount of the pre-cavity amp gain. This should still achieve some net expansion of the low end range.

9112. Pre-cavity VGA

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-29 14:53:32 UTC
From: Sam
Topic: 9112 Message: 9112

I have a couple of reservations about the idea of using a VGA (such as a fixed amp + PIN attenuator) prior to the cavity filter. The main issue is that the phase shift of the VGA likely varies considerably over signal level. Crudely speaking, anything done at 1 GHz is likely to have 100 times the phase effect of the same thing done at 10 MHz. Presently, if you do Phase Calibration, you may get a few degrees of variation over signal level, until you get to fairly low signal levels. That means you may get very useable phase info without any Phase Calibration. I think with the PIN diode attenuator you may get 50 or 100 degrees of variation over signal level. This not only makes the phase info meaningless without Phase Calibration, but possibly also makes phase very sensitive to the temperature of the diodes in the attenuator.

The PIN attenuator or other VGA mechanism might not be as effective if placed before or after the IF2 amp, but at least there it would operate at 10.7 MHz where the phase effects would be far smaller.

Ideally, the PIN attenuator control would cause it to reach max attenuation somewhere below -90 dBm, where precise phase measurements are normally not possible anyway.

Finally, any amp prior to the RBW filters must be able to handle strong signals outside the RBW at minimum attenuation/max gain, because the log detector will be unaware of such signals and therefore its output may remain low and it will not be increasing attenuation/reducing gain in order to deal with the strong signals. This limits the max feasible pre-RBW gain.

Sam W.

Sam
I put a phase measurement over the range here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/714983641/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc

The phase variation over -11dB to -22dB (Vctrl 0.5V to 2.0V) is about 28 degree.

From: inlinebeginner
Topic: 9112 Message: 9114

Instead of put pre-cavity VGA, we may want to put a preCavity AMP + 1bit switchable attenuator to shift the orginal MSA V-dBm curve 10dB down for weak signal test. That would double the calibration work.
I was wondering if we can design a auto calibration tool to do the calibrion. Every 1 year we may need to recalibrate the MSA, that might be the time we just forget how to do the calibration. If we can automate the calibrition, it would be nice.

9117. Simple Photos

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-30 11:15:48 UTC
From: Sam
Topic: 9117 Message: 9117

In order to get good closeup photos of circuit boards, I have used a fancy digital camera with a macro lens, but I still don't get good depth of field. So I tried photos with my IPad 2, which normally takes very clear pictures. However, it is a bit "far-sighted" so if you take pictures of something only a few inches away the fine details can be very fuzzy. That far-sightedness is the reason most cameras require a macro lens for extreme closeups.

I have a very cheap magnifying glass, about 2" in diameter, that has a small area of extra magnification near the handle. I held that over the IPad lens while taking the picture (tight against the IPad body), and the results were amazingly good. See attached photos, one with and one without the magnifier. The black towers in upper right and lower left are jumpers, which project out toward the camera about 1/4" but still come out clear.

I'm sure the same thing could be done with a phone camera. I intend to buy a stronger magnifier, or maybe powerful reading glasses (+1.25 glasses had little effect). And to figure out how to hold the IPad a bit steadier.

I did this in the middle of the night. I woke up with this idea and had to try it out.

>In order to get good closeup photos of circuit boards, I have used a fancy digital camera with a macro lens,

Hi Sam

If you want to take high def macro picture with a infinite field depth, there is a nice technique called □light scanning photomicrography□. You must generate a very thin □line□ of white light (a dia projector with a □slotted□ cache made with old razor lames), a sliding support and a camera able to take a picture with an □infinite aperture time□ . Results are fantastic

http://sebaw.online.fr/eng/technique.htm

http://comiti.com/

There is another trick to have high def pictures of pcb□s : the scanner. If you have a flat bed scanner, you just have to put your board on the front glass and scan it. It□s a cheap □macro□ engine. Depending on the quality of your scanner, you can have a higher def than any macro lens ;-)

I have done really nice close ups with inexpensive Cannon and Fuji pocket cameras. I have very high dollar Nikon's with several macro lenses if needed but these cameras are very convienent to have in shack verses large SLR and heavy lense's. I did not pay more than $99 for either of the small cameras. The auto focus when set to macro also worked very well. I did not need flash just average room light.
I did adjust white balance for available room lights,IE, flurescent in shop. Depending on lighting arrangement you may need some supplemental light if your head and camera blocks available light.

9120. Slim-adc or slim-pdm power supply ?

Yahoo group: spectrumanalyzer (2011)

From: marc olanié
Topic: 9120 Message: 9120

Hi
Two options can help to have a better phase accuracy. The firt one, described at

http://www.scottyspectrumanalyzer.com/slim_ADC_16.html

paragraph "Optional Power Modification to SLIM-ADC-16...

uses the 5 Vcc delivered by the PDM

BUT...

MOD 4 chapter of the Slim PDM says the opposite, and ask to add the 5V regulator to the ADC and use it to power only U5 of the pdm

redo from start, cyclic redundancy error, same player shoot again :- D

Which is the "best solution" ? I would say the second one, looking @ modification's date, but I need to be shure

Thanks

Marc

Whichever is most convenient is the way to go. The important thing is that the ADC and the final flip-flop in the PDM have the same power supply. There was a bit of discussion of this recently, so you might search the messages.

I used the ADC supply to power the final PDM flip-flop, which also requires cutting a trace to separate that IC from the PDM supply.

The thing I like about using the iPad or phone is you can email the pictures to yourself or someone else, or put them in DropBox, without hooking to your PC or using a flash card as an intermediate step. For about $15 you can buy an assortment of 4X-12X magnifiers, so I may give that a try. (Large magnification may be nice, though I suspect it gets you back to limited depth of field.)

BTW, I have an inexpensive scanner that produces beautiful scans, but has very limited depth of field so it doesn't work well for circuit boards (except bare ones). Plus, I don't use it a lot so when I do I have to dig it out of the closet and hook it up.

I use a Panasonic Lumix dmc-fz50, with a simple screw-on close up lens and tripod. This combo works fantasically well! This camera is now outdated and is more pricey than some other possible options, however, it has taken thousands of great photos for me! Note that a tripod *really* helps when wanting to get close, clear detail.

See a sample photo of the bottom of a GE Rangr VCO board at:
http://12.17.28.4/~kb4fxc/rangr/Rangr89-6m-conversion/photos/p1010200.jpg

Jurgen,

A cheap USB microscope from Ebay will do nicely.

I'm also using it when soldering smd's manually.

I paid 25 odd U$ or so. I think it can do 100x.

I uploaded some photos taken as a demo to the group photo's in the new M0DFI folder.

Theres a close up, medium range and well from above. The microscope do well as a webcam.

And here is my contribution to the subject:

I use a regular digital camera in the telefoto setting were you get
maximum depth of field to avoid having to worry about the focus.
I also use a USB cheap digital microscope for inspection with about x80
magnification. It's amazing to see the images on a 17" monitor full screen.

Another technique that could be used is called focus stacking. I haven't tried it, but keep saying I'm going to experiment a bit.

The idea is that you take three photos, one with the foreground in focus, one with the middle in focus, and one with the background in focus, then post-process the three photos with software.

There is a wikipedia article here
http://en.wikipedia.org/wiki/Focus_stacking

There are even some electronic gadgets you can build to help. One is here
http://www.circuitsathome.com/camera-control/focus-stacking-assistant-for-eos-cameras

Apparently the site owner uses the technique to take a lot of the photos on the site.

"Taking photo's of PCB"?

What are your intention with the photo's? Advertizing on house wall sized billboards.
Or married to an article in a magazine or just a pesonal archiving matter...

You don't really need a 1.8 Giga Pixel camera unless you intend to spot PCB's in a pocket of a Taliba :)
Nor do you ned a 10-15 MP camera for an article in a radio/electronics magazine.

I guess my USB camera gives me a minimum of 640x320 but I suspect I get 1024x768 pixels out of it.

The USB camera pictures are good enough for the article but not for the wall ad.

It's not just a case of my usual Saturday morning grumpiness but I just wanted to higlight the
difficulty on giving you a good answer to your question.

I mean - yes, I'd like a Hasselblad 200,000 MP camera but it would be wasted on what I do.
PCB pictures in HD? Nahhh!

//Cheers

9132. building the video filter SLIM

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-31 16:29:38 UTC
From: Geoff
Topic: 9132 Message: 9132

I am about to upgrade the software from an early version of 116 to the latest version that incorporates the USB facility and software controlled switches.

I would at the same time, install the software controlled video filter selection SLIM.

Has there been a group buy for this SLIM pcb that I missed or is it combined with another group of pcb's ?

Looking at the schematic, it appears that connection to the ADC board is via a single coax for each of the magnitude and phase lines. The original, which I have, used capacitors on the ADC pcb and an external switch.

How is the new pcb connected, I can only imagine that a SMA tee is used to connect the new pcb coax to the existing.

My final question (at this time) concerns a possible typo in the notes associated on the video filter schematic rev B , 1/10/2011, which says that the larger filter caps have series caps to avoid damage on power down. Should these be series resistors ?

Hope you all have a successful 2012, and all your projects work first time.

Geoff

Geoff,
It was included in a group buy of a larger board some time ago. There were some errors in that PCB that were communicated to the participants.

The video filter switch connects to the ADC board with a single wire for each of mag and phase. Coax is also fine. The switch just appends a grounded capacitor to the end of the line, so no thru connection is needed.

You are correct that the large capacitors have series resistors, not caps. This is to limit current discharge through improper paths on power off; whether they are actually necessary is anybody's guess. I have actually reduced my resistor values to 22 ohms, though I'm not sure that provides any advantage over 47 ohms.

Be sure to run the Configuration Manager to tell the MSA that you have implemented the automated video switch.

Sam,

Thanks for the very prompt response, looking at the schematics of both the video filter switch and the ADC, I think I could connect the centre of the coax connectors on the switch board to the connector on the ADC that I am currently using for the centre pole of the manual switch.

Next, I don't suppose that anyone has a spare board that contains the video switch pcb they can part with.

I use a cheap x400 USB "Microcapture" with manual focus.
Only occasionally I need to add an external light source (flashlight) to read those tiny SMD ID codes. Great at finding solder bridges or not well soldered pads.
